THE deaths of infants under one year of age in Ireland during last year did not exceed 92 per 1000 registered births, showing a decline of 1 per 1000 from the rate in the preceding year; this rate compared very favourably with the rate of infant mortality in England and Wales, which during last year was equal to 118 per 1000. In the 22 town districts of Ireland the rate of infant mortality in 1907 was, however, equal to 135 per 1000, whereas in the 76 largest English towns the rate did not exceed 127, and in 142 smaller English towns the proportion was only 122 per 1000. This high rate of infant mortality in the urban population of Ireland affords evidence of the neglect of organised sanitation in Irish towns, which is corroborated by their general mortality statistics, to which attention was recently drawn in the special report on the health of Belfast. The low rate of infant mortality in the Irish rural districts shows, however, the general care of infant life by Irish mothers. It appears that among the entire Irish population, exclusive of the 22 town districts specially dealt with in the returns of the Registrar-General for Ireland, the rate of infant mortality during 1907 was so low as 72 per 1000.

VENEREAL DISEASES IN CHRISTIANIA IN THE YEAR 1907.

COMPULSORY notification of venereal diseases in Christiania has existed for many years and the annual report of Dr. Ustvedt, medical officer of health of Christiania, in the *Tidsskrift for den Norske Lægeforening* of Sept. 15th shows the marked fall in all forms of venereal disease except hereditary syphilis. Of the 1567 cases notified in 1907 gonorrhœa claimed 1015 (903 males, 112 females, including five under the age of 15 years); soft chancre, 143 (133 males, 10 females); acquired syphilis, 374 (251 males, one under 15 years, 123 females, two under 15 years); and hereditary syphilis, 35 (10 males, 25 females). In 1906 the number of new cases was 1889, while in the worst year, 1882, the number was 2533; in fact, 2·07 per cent. of the whole population, whereas the percentage for 1907 is only 0·68. Of the cases of acquired syphilis, extra-genital infection occurred in 20, two of which also had a primary sore on the genitals. The seat of infection in these cases was as follows: throat, one; tonsils, two; gums, one; lips, six; finger, one; a point ten centimetres above symphysis pubis, one; penis and point just below nipple, one; and penis and lower lip, one. In six cases the seat of the primary sore is not given. 14 women traced the infection to their husbands, and five men pleaded infection from their wives. In consequence of notification the medical officer of health and a lady medical practitioner examined 25 men and 64 women, one man and eight women having to be summoned by the police. One man refused to be examined; one man and three women refused to attend at the medical officer's quarters. Certificates from other medical men were obtained by 12 men and 12 women, of whom seven men and five women were declared diseased. 12 men and 25 women, including some children, were examined owing to their close association with infected cases; infection among these was detected in four women. Further, 314 men and 130 women have voluntarily presented death may be said to have been due to a complication rather than to the actual infective process. The issue and duration of the phase would appear to have been determined by the quality and site of the exudate, and by its fate—that is to say, by the question of its resolution or organisation.

Gross lesions such as these are a menace in themselves, apart from bacterial activity; and it is not to be expected that an anti-microbic serum can influence their course to a useful extent once they have become established. The remedy is prophylactic. Serum must be given sufficiently early to prevent their occurrence. This view is in agreement with our finding that serum-treated survivors of the first ten days of illness had a better prospect of recovery than untreated cases.

HOSPITAL AND MEDICAL SCHOOL DINNERS.

St. Bartholomew's Hospital.—The annual dinner of the old students of St. Bartholomew's Hospital was held in the Great Hall on Oct. 1st, under the presidency of Mr. H. Gilbert Barling, Dean of the Medical Faculty of the University of Birmingham. Among the guests were Inspector-General James Porter, C.B., Director-General of the Royal Navy Medical Service, and Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Service; Dr. H. A. Miers, Principal of the University of London; the Rev. Dr. Gow, head-master of Westminster School; and about 150 old students, among whom were Mr. Howard Marsh, professor of surgery in the University of Cambridge, and Dr. George Wilks, Master of the Society of Apothecaries. After the usual loyal toasts that of "The Imperial Forces" was proposed by Dr. W. P. Herringham and responded to respectively by Inspector-General Porter and Sir Alfred Keogh. The toast of "The Visitors" was proposed by Dr. Norman Moore in an eminently characteristic speech full of sound learning and wit and responded to by Dr. Miers and the Rev. Dr. Gow. One notable feature of the evening was the way in which the idea of compulsory military training was advocated by many speakers and received with loud applause. The speeches were all good and commendably brief and after dinner an adjournment was made to the magnificent new pathological block which has just been opened.

St. George's Hospital.—The opening of the autumn session at St. George's Hospital was marked this year by the inauguration of the new St. George's Hospital Club. A large number of past and present students crowded the lecture theatre, where Sir William H. Bennett was in the chair and gave the new club a send-off that promises well for its future success. In the evening the annual dinner was held under the chairmanship of Dr. T. T. Whipham, consulting physician to the hospital, and a record number of St. George's men enjoyed themselves in the manner traditional to the first of October.

London Hospital.—The annual dinner was held at the Savoy Hotel on Oct. 1st. The chair was occupied by Dr. A. J. Rice Oxley, and amongst the 180 old students and others who sat down to dinner were Sir Frederick Treves, Bart., G.C.V.O., C.B., Sir R. W. Burnet, Sir Cecil Trevor, C.B., Mr. Jonathan Hutchinson, and Colonel W. F. Cavaye. After the loyal toasts had been duly honoured Dr. Rice Oxley, in proposing the toast of the evening, "The London Hospital," spoke with pride of the progress which the institution had made since he had first entered it as a student 30 years ago. Progress was the watchword of the house committee and it had lately appointed some lady almoners to the out-patient department, whose duties would be to prevent hospital abuse and to keep the hospital in touch with the activities of various external charities. The entries to the medical school were keeping up even whilst those of the majority of other metropolitan schools showed a decline in numbers. Finally, he recommended all with rich patients to interest them in the Medical College Endowment Fund. In replying, Mr. Douro Hoare, chairman of the college board, alluded to the sad loss of Mr. Harold Barnard and dwelt upon his heroism in working up to a couple of months before the end without a murmur, although himself suffering and knowing the nature of his disease. After referring to the early days of the hospital Mr. Hoare said that the ambitions that actuated those early governors still animated those of the present day—viz., to succour the sick poor of Whitechapel, to advance medical and surgical knowledge and research, and to train the best students. For the present work of the hospital Mr. Morris, the secretary, should be consulted. The toast of "The Chairman" was proposed by Dr. A. Mantle and suitably acknowledged, and after Mr. Jonathan Hutchinson had responded to a universal request for a speech by thanking the old students for so honouring him and expressing the pleasure and interest which these dinners gave him year by year the meeting broke up.

St. Mary's Hospital.—The annual dinner of St. Mary's Hospital medical school was held in the Whitehall Rooms on Oct. 2nd, Dr. A. P. Luff being in the chair. Amongst those present were Surgeon-General Sir Alfred H. Keogh, Inspector-General James Porter, Sir Anderson Critchett, Sir Malcolm A. Morris, Mr. H. A. Harben, Mr. G. A. Byron, with many members of the staff and past and present students of the hospital. The dinner was successful in every way and was aptly described by one of the speakers as "a family gathering." The toast list was, by the chairman's benign ruling, commendably short, comprising only "The King" and "St. Mary's Hospital and Medical School," given by the chairman and responded to by Mr. Harben, chairman of the hospital board, and Mr. W. H. Clayton-Greene, dean of the medical school; and "The Visitors" proposed by Dr. W. J. Gow and responded to by Sir Alfred Keogh. Dr. Luff, in his speech, paid a distinguished tribute to Mr. Harben's untiring work for the hospital and especially to his success in coördinating the aims of the medical and lay elements of the board of management; he also referred to the remarkable success of the Hospital Rifle Club in winning the four trophies which decorated the high table. The dean, in replying, gave a list of conspicuous academical honours won by the school during the last year and spoke of the neglected responsibility of the State in the medical education of the country. Sir Alfred Keogh, in replying for the visitors, said that he was not a stranger to St. Mary's, for he had chosen that hospital for a course of post-graduate study after his return from service abroad, as he considered it to be the most progressive hospital in London. During the evening Mr. Byrd-Page gave an amazing performance called "My Hands and Your Eyes," which added considerably to the gaiety of the gathering.

St. Thomas's Hospital.—The annual "Old Students" dinner took place on Oct. 2nd at the Savoy Hotel, Mr. Thomas Wakley being in the chair, supported by a large company, including Mr. J. G. Wainwright, J.P. (treasurer of the hospital), Dr. J. F. Payne, Dr. S. J. Sharkey, Mr. H. H. Clutton, Dr. H. P. Hawkins, Mr. G. H. Makins, Dr. Hector Mackenzie, Mr. Bernard Pitts, Mr. W. H. Battle, Mr. H. Betham Robinson, Dr. W. W. H. Tate, Lieutenant-Colonel J. Lees Hall, R.A.M.C., Mr. D. K. Macdowell, C.M.G., Lieutenant-Colonel H. E. R. James, R.A.M.C., Dr. L. W. Sedgwick, Dr. J. F. Priestley, Mr. F. G. Hallett, Mr. Cuthbert S. Wallace (dean of the medical school), Mr. G. Q. Roberts, and Mr. J. E. Adams and Dr. M. A. Cassidy (secretaries of the dinner committee). After the loyal toasts had been duly honoured the chairman, in proposing the toast of "St. Thomas's Hospital and Medical School," pointed out that since the year 1875, when he entered as a student at St. Thomas's Hospital, the discoveries and advances in connexion with medicine and surgery had been of such a remarkable nature as practically to transform both the hospital and the medical school. In those days antiseptic surgery was in its youth. With regard to the days that had since elapsed he was reminded of the well-known line "Felix qui potuit rerum cognoscere causas." In that comparatively brief space of time it had been the happy lot of the profession to learn the causes of many of the diseases which afflict mankind, to obtain knowledge of, for instance, the pathogenic agents of tuberculosis, of diphtheria, of tetanus, and of syphilis, and of the mode of the spread of malaria, yellow fever, sleeping sickness, Malta fever, and other devastating tropical diseases. Then, again, the introduction of serum therapeutics and vaccines, the discovery of the Roentgen rays and of radium, and the work of Finsen and others with regard to the therapeutics of light had resulted in new and often very technical methods of treatment. He had no hesitation in saying that in the journey along the paths of scientific progress St. Thomas's Hospital and its medical school could challenge comparison with any of the great medical institutions. The toast was responded to by the treasurer, Mr. Wainwright, and the dean, Mr. Wallace. The former alluded to the many years that had elapsed since he first assumed the duties of his office and the many improvements that had been effected during that period. He concluded with a sympathetic reference to the loss which they had sustained by the death of Dr. Cullingworth. The dean (Mr. Wallace) urged the long-felt necessity in London for "an average degree for an average man," the granting of which he hoped would no longer be opposed by existing graduates, and mentioned the fact that a lying-in ward would in all probability soon form part of the hospital. The toast of "The Chairman" was proposed in humorous terms by Dr. W. J. Sheppard and suitably acknowledged.

after thorough mixing, for 12 hours. Dilutions were then made exactly as described for the original sewage, cultures made with 1 cubic centimetre, and incubated as before. The results are embodied in the following table :—

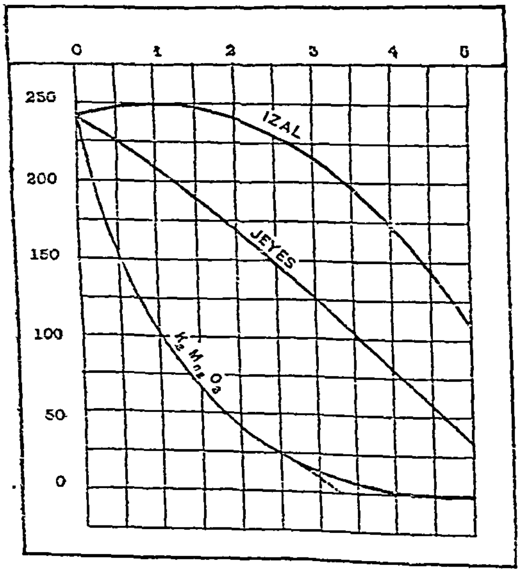
Colonies in 0·00001 Cubic Centimetre of Sewage after Treatment for 12 hours.

—	A	B	C	Average.	Corrected Average.	Conspicuous liquefiers.
Untreated sewage	185	250	279	239	239	9
$K_2Mn_2O_8$, 1-5000	83	94	93	91	99	1·3
,, 1-2500	20	28	16	21	23	0
,, 1-1000	1	0	2	1	1	0
Jeyes', 1-5000	193	165	193	192	209	10
,, 1-2500	156	106	142	134	147	7
,, 1-1000	36	25	30	30	33	2
Izal, 1-5000	252	237	224	237	261	11
,, 1-2500	209	200	226	212	233	8
,, 1-1000	101	110	92	101	111	8

The "corrected average" is made to allow for the amount of disinfectant added, which, of course, reduced the proportion of bacteria to the extent of 9 per cent.

Three strengths of disinfectant having in each case been taken it became possible to construct a curve from which the effect of other strengths could be calculated, and this is given below. It shows in the most interesting way that whilst the disinfectant action of Jeyes' fluid was proporportional to the strength of the dilution used in the case of izal the disinfectant action increased rapidly as the strength was increased, whilst with permanganate the effect ceased to increase as soon as a strength of 1 per 1000 was reached. It is, of course, to be noted in this connexion that whilst permanganate was used in the solid form, in the case of the other agents used the dilution was made from a solution, so that the results are to be interpreted accordingly. The experiments made thus pointing to permanganate as at once the strongest and cheapest agent of the three for the purpose in view, the next point was to test intermediate strengths of it, since the curve appeared to indicate that the maximum effect was reached while the dilution was weaker than 1 per 1000, as shown by the dotted line in the curve, and the time element was doubtful. The results were as follows :—

Parts of Reagent per 5000 of Sewage.



—	5 minutes	15 minutes	1 hour	2 hours	4 hours
Raw sewage	243	—	—	—	—
Permanganate 1-5000 ...	54	56	56	64	51
,, 1-4000 ...	2	1	2	1	2
,, 1-3000 ...	0	0	0	0	0
,, 1-2000 ...	0	0	0	0	0
,, 1-1000 ...	0	0	0	0	0

The fact that the results in this case were even more favourable than in the preceding series is probably attributable to the circumstance that the sewage consisted of a stool and urine, with a two-gallon flush, and not, as in the previous case, of natural sewage. The whole was intimately mixed, as before. Graduated quantities of a strong solution were also used instead of 1 cubic centimetre of a ten-times strength, so that the actual dilution was slightly stronger than before.

It was made abundantly clear that the time-element was of no importance whatever. It has been the fashion to say —upon what basis other than an *a priori* one it is difficult to imagine—that the presence of organic matter interferes with the disinfectant action of permanganates. If this be so, it appears to be a negligible factor, or, as seems more probable, the highly complex proteid of the bacteria succumbs more rapidly to the attack of the nascent oxygen of the permanganate than the less complex materials by which it is surrounded. It would seem clear also that since a solution of permanganate of a strength of 1-1000 is about the least that will completely deodorise such a mixture as that used in the experiments, we have at command a convenient rough-and-ready test of sterility. It seems safe to say that if such a mixture be deodorised completely it is also sterilised.

As regards the experiments as a whole, it may be said that for the purpose in view the Rideal-Walker method must have failed to be of service; and indeed, whilst the ideal mode of testing disinfectants has yet to be evolved, it would seem that the only safe method of procedure is to approximate the conditions of the test to those of actual practice. It is one thing to test disinfectant action on organisms suspended in sterile salt solution and another to take the organisms in their natural habitat and see what will kill them there. Moreover, the fact that the suspension of the organism containing the latter plus the disinfecting agent is transferred, without further dilution, to the culture medium and absorbed by its surface seems a distinct source of error. In the method detailed above it will be seen that the disinfectant was in each case diluted to 1–100000 of the strength at which it had been allowed to act for the purposes of the experiment, so that this cause of error was eliminated. The method is no doubt antiquated but it is not necessarily worthless for that reason, nor is every more modern one necessarily preferable. Moreover, the construction of graphic curves is, in the Rideal-Walker method, quite excluded.

Camberwell, S.E.

Reviews and Notices of Books.

Précis de Pathologie Interne. (*Précis of Internal Pathology.*) Par MM. BALTHAZARD, CESTAN, H. CLAUDE, MACAIGNE, NICOLAS, et VERGER, Professeurs agrégés des Facultés de Médecine. Paris : G. Steinheil. 1907. 4 vols.: vol. i., pp. 829; vol. ii., pp. 676; vol. iii., pp. 947; and vol. iv., pp. 868. Price complete 32 francs.

THE preface to this work, which is in effect an important text-book of medicine, is written by Professor C. Bouchard, who states that it is the product of six men who, having studied together and having similar ideals, have combined to produce a text-book which shall be at once scientific and practical.

The first volume is devoted to the infectious diseases, which are described by M. Nicolas of Lyons, and to the intoxications, the account of which is contributed by account for the rise. He seems to think, however, that the bacillus of enteric fever can retain its virulence for long periods in the walls of privy middens, and he regards evidence that he adduces as suggesting that the middens begin in July to exercise a special influence on the propagation of enteric fever which increases in August and culminates in September. He then proceeds to ask how far a theory that the house-fly is the agent of transmission of the bacillus is supported by facts. He finds that in Manchester the number of cases of enteric fever begins to ascend four to five weeks after a considerable increase in flies and two weeks after a marked increase of deaths from diarrhœa. But after further detailed consideration he expresses a doubt as to how far flies do actually act as a source of infection and he proceeds to discuss the food factor. Watercress he dismisses as improbable and his mental attitude with regard to lettuces, celery, and fruits is a similar one. The influence of shell-fish, especially mussels, is discussed in considerable detail, but Dr. Niven finally comes to the conclusion that the contribution from shell-fish is essentially secondary. To the summer and autumn holiday period some influence is, he concludes, ascribable, but the factors are so complicated that it is difficult to measure the influence. Dr. Niven does not regard the previous prevalence of diarrhœa as bearing much relation to the subsequent enteric fever, and he is unable to add any facts as regards the interesting question of seasonal predisposition—i.e., whether the climatic effects of season predispose the body to attack in autumn—but he evidently suspects that the high degree of infectivity which attaches to cases of enteric fever in autumn and winter may be an important factor in bringing about the seasonal rise in the disease. Dr. Niven sets out his purely provisional conclusions seriatim but they would occupy too much space to reproduce. His recommendations embody the abolition of pail closets and middens, effectual house drainage, protection of foods, manure, and refuse from flies, the substitution of refuse tips by destructors, the registration of sellers of shell-fish, and the discovery of overlooked cases of the disease. Perhaps the last factor ought to be placed first. Dr. Niven's report abounds with discussions of epidemiological interest, but as the volume runs to over 300 pages the report itself must be consulted. The Manchester Milk Clauses were vigorously applied during 1907 and 700 samples of mixed milk were examined for tuberculosis. These milks came from Cheshire, Derbyshire, Staffordshire, Lancashire, Shropshire, and Yorkshire, the number of farms which sent tuberculous milk into Manchester ranging from *nil* to 12·5 per cent. The tuberculous mixed samples were followed up and 28 cows were found to be suffering from tuberculosis of the udder. Of these cows 21 were slaughtered in the presence of the veterinary surgeon and in five cases the whole carcass was passed as fit for food, in two cases parts of the carcass were passed, and in the remaining 14 the whole carcass was condemned.

The City of Edinburgh.—The population of the Scottish capital for 1907 was estimated at 345,967. The birth-rate was only 21·6, a rate markedly below nearly all the large towns of England and Scotland during the same year. In 1890 the birth-rate of the city began to fall and since then it has steadily declined. Sir Henry D. Littlejohn does not discuss the matter in relation to age, sex, and class distribution. As regards the death-rate, it was heaviest in the first quarter and lightest in the third, the rate for 1907—14·4 per 1000—comparing favourably with the other large towns in England and Scotland. Aberdeen and Bristol both had lower rates. The popularity of the fever hospital appears to be on the increase judging from the percentage of the total number of notified cases of scarlet fever, enteric fever, and diphtheria which obtained admission. The increase has been most marked in the case of diphtheria, the percentage of admission being double that which obtained nine years ago. There was, too, in 1907 a marked difference in the fatality rate of those cases treated inside and those treated outside the hospital, the former rate being 4 per cent., the latter 12 per cent. Dr. Claude B. Ker in his report for the city fever hospital furnishes some interesting data. The number of cases admitted for diphtheria was 546, but subsequent experience seems to have shown that 67 were cases of tonsillitis. In many of these cases the diphtheria bacillus had, it was stated, been found prior to admission, but none could be found subsequently and the clinical appearance of the cases did not justify the diagnosis of diphtheria. Of the other cases, seven were cases of scarlet fever and two secondary syphilis. As regards enteric fever, of the 91 cases sent in as enteric fever only 69 were found to have the disease. The experience of 1907 in the matter of cerebro-spinal fever is instructive. Of 122 cases notified as suffering from that disease 112 were found to be so suffering and of these 88 died, the fatality rate being 78·57 per cent. Of the patients 43 per cent. were under five years of age and 81 per cent. under 20 years of age. 22 of the patients died within 24 hours of admission. Post-mortem examinations were made on 34 of the patients and, even after two or three days it was common to find the brain and spinal cord thickly plastered with purulent matter. The relief afforded by drawing off the purulent fluid from the spinal cord was only temporary and drugs were but of little avail. Hot baths were found to be most efficacious in assuaging pain and the children were found to be crying for their baths, which were given three times daily. None of the serum employed gave very satisfactory results except that of Dr. Simon Flexner of New York, which was moderately successful. Dr. Ker discusses the question of the so-called cross-infections in fever hospitals. In his view such cases are not due, as is sometimes believed, to the carriage of infection from one ward to another by attendants, an event which in his experience is extremely rare. He attributes the phenomenon to the introduction of patients with two diseases running concurrently or by the introduction of cases wrongly diagnosed. Or again, a patient introduced with one disease may be incubating another. Dr. Ker gives illustrations of all these methods and he furnishes a rather formidable list of persons who admitted for one disease contracted another. There are some wards in the hospital for pulmonary tuberculosis and during 1907 130 cases were admitted to them, the cases being mainly those of an advanced type. We cannot close this brief notice of Sir Henry Littlejohn's last report without an expression of deep regret at his retirement from the position which he has held for so many years and of our appreciation of the eminent services which he has rendered to preventive medicine.

County Borough of Blackpool.—Dr. F. J. H. Coutts, in the course of observations on the question of infantile mortality, states that it is astonishing to find the trivial reasons which are sometimes advanced to induce mothers to discontinue suckling and he adds that some monthly nurses and midwives are too ready to assume that the mothers' milk is insufficient and that it is necessary to use some patent food which has been sent to the midwife by an advertising firm. The female inspector who has recently been appointed is, Dr. Coutts observes, frequently encountering the problem of the unwanted, illegitimate child. In one case it was ascertained that the child had been in nine different homes during its life of ten months, while another, three months old, had been in three different homes. The experience of Dr. Coutts is to the effect that supervision over homes where one child is kept is as necessary as over homes where several children are taken.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8396 births and 4139 deaths were registered during the week ending Oct. 3rd. The annual rate of mortality in these towns, which had steadily declined in the six preceding weeks from 15·8 to 13·2 per 1000, was equal to 13·3 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 13·4 per 1000, and in London the mean rate in the same period did not exceed 12·5. The lowest annual death-rates in these towns during the week under notice were 5·6 in Hornsey, 6·1 in Smethwick, 6·6 in Willesden, and 6·7 in West Hartlepool; the rates in the other towns ranged upwards, however, to 18·6 in Preston, 18·9 in Tynemouth, 19·6 in Salford, 21·3 in Rotherham, and 21·4 in Bolton. In London the death-rate during the week did not exceed 12·2 per 1000. The 4139 deaths from all causes in the 76 towns showed an increase of 24 upon the number in the previous week, and included 521 which were referred to the principal epidemic diseases, against numbers declining from 1343 to 527 in the five preceding weeks; of these 521 deaths, 363 resulted man *for drinking or domestic purposes*. In Manchester it is the same, while in Birmingham the distance prescribed is 40 feet, in Dublin 10 feet, and in Belfast 5 feet. On the question of ash-bins there is again a great diversity in the regulations, as also in the case of certain objectionable fittings such as various forms of closets and traps.

The study of these by-laws has been of interest to us, for in the Report of THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work, which was published on July 4th, 1896, there is scarcely a single thing now prohibited by these by-laws on the one hand, or made imperative to be performed on the other, that was not either condemned or recommended by the Commissioners of THE LANCET 12 years ago.

LIBRARY TABLE.

The Soul of Spain. By HAVELOCK ELLIS. London: Archibald Constable and Co. 1908. Pp. 419. Price 7*s*. 6*d*. *net*.—This is an interesting book and Mr. Havelock Ellis manages to justify his rather romantic title in an unmistakable way. He deals hardly at all with the political, industrial, or commercial aspect of a country which he obviously loves, and does not even allude to Spanish achievement in medicine, for these he considers to have a bearing only on the physical side of Spain; but devotes his time and highly trained powers of attention to the interpretation of certain aspects of the Spanish spirit, as manifested in literature, art, ethics, and behaviour. This spirit he finds characterised by "an attitude of heroic energy, of spiritual exaltation directed, not chiefly towards comfort or towards gain, but towards the more fundamental facts of human existence"—an estimate of Spanish efforts and ideals, which he certainly tells us much to justify, but which is distinctly opposed to the popular notion. The author has, however, journeyed up and down the country on several occasions and during a long extent of time, and throughout the whole period he has been meditating over and revising his impressions, so that with growing familiarity he might remove his prejudices. This is, of course, the best of all ways to get a clear view of essential facts, and the impression left upon the reader by this interesting work is that Mr. Ellis has spared no pains to make his diagnosis of the Spanish character a true one. Much of his thesis is certainly borne out by the literature and art of Spain, though the painters, dramatists, and novelists of other countries have usually introduced the Spaniard, especially the female Spaniard, into the story or on the canvas, merely in order to display the stereotyped qualities of the erotic, brilliant, and cruel. The chapter on the women of Spain is made particularly interesting by the anthropological insight displayed, and medical men on reading this section of the book will probably acquiesce in the author's psychology, though the result is to bring before them a very different person than that heroine of Merimée's novel whom Bizet has helped to immortalise. Of Velasquez and Cervantes Mr. Ellis has many things to say, of the sort that no one can contradict, and some things which have been said many times before, but he will be found here a clear and responsible guide to sound judgments. Whether his implicit belief in the essential nobility of the Spanish character rests upon a sound psychological basis or is the outcome of a fascination which he does not seek to disguise, we are not able to say. But we recommend the book to our readers, suggesting that a volume, when ably written and with honest conviction, often gains in interest by its ability to arouse a little opposition.

The Cathedrals of Norway, Sweden, and Denmark. By T. FRANCIS BUMPUS. London: T. Werner Laurie. 1908. Pp. 295. Price 16*s*. net.—Mr. Francis Bumpus has written four or five books already upon the cathedrals of different countries, several of which have been reviewed in our columns. He has hitherto treated districts that may be assumed to be familiar to all who have travelled—France, Germany, and Italy, for example—so that he was appealing to a large audience who had seen the things which he was describing; he had also another large audience who hoped to see those things soon, for there must be few among us in these days of rapid journeys who have not formed an intention of seeing the cathedrals, say, of Chartres, of Cologne, and of Florence before they die. Now, however, Mr. Bumpus takes us to lands quite familiar to many sportsmen but not much frequented by the artist or archæologist, so that his task of interesting the public is more difficult. The ecclesiology of Norway, Sweden, and Denmark has hitherto been but little regarded and the author has been unable to get the assistance of any published work dealing with it in a general manner. So that he is addressing readers who for the most part have not seen the cathedrals in question, who also have not seen pictures of them, and who, lastly, will find that the most salient characteristics of the buildings are not those which call for admiration at Rouen, say, or Siena. No Danish Romanesque church, for example, is at first sight beautiful; the cathedral at Trondhjem, a mixed Gothic and Renaissance structure, which, as Mr. Bumpus says, is the architectural pride of Norway, has been restored out of recognition, and its grand and lovely interior has to compensate for its external appearance; Upsala Cathedral, which appears to be the most important cathedral in Sweden, is a very unsatisfactory Gothic erection. It is quite certain that some such uncomplimentary reflections as the foregoing will be the first to rise to the lips of those who see the buildings. But Mr. Bumpus is a painstaking and enthusiastic *cicerone*. He shows us how to look at these rather novel structures and balances their internal beauty against their faults of exterior. He has also mapped out in his book a circular tour for travellers wherein the great cathedrals are but episodes. He points to the beauties of many less conspicuous churches and cathedrals and the result of reading his book should certainly be to make us want thoroughly to explore such buildings as the cathedrals at Roeskilde, Lund, and Strengver. The long holiday is becoming more and more of a necessity to medical men, as the stress of modern life compels them to transact their business under ever-increasing pressure. There are many reasons why they should go to Scandinavia, and it appears from Mr. Bumpus's book that one of these, hitherto unsuspected, is the interesting nature of the church architecture.

Rational and Effective Treatment of Hip Disease. By P. BRUCE BENNIE, M.A., M.D., B.S. Melb., Honorary Medical Officer, Melbourne Hospital for Sick Children; President of the Melbourne Medical Association 1896; President of the Melbourne Pediatric Society 1907. Founded on experience of numerous cases in hospital practice during 28 years. Compiled by ALEXANDER B. BENNIE, M.A., M.B., B.S. Melb. London: Baillière, Tindall, and Cox. 1907. Pp. 108. Price 5*s*. net.—The object of this work is to bear witness to the value of the Thomas method of treatment of hip disease. The author holds that the Thomas splint is the only contrivance by which complete rest can be given to the joint and thus the disease can be arrested. He insists, however, that the splint as usually supplied by instrument makers is not that which was invented by Thomas. Full directions are given for measuring a patient for the splint and for making it. The fitting of a Thomas splint is nearly always left to the instrument maker and he employs a routine method. Dr. Bennie may be followed safely by those who wish to get the best results from splint treatment.

a Professor, vice Lieutenant-Colonel A. M. Davies, retired (dated Sept. 17th, 1908).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel William B. Day is placed on temporary half-pay on account of ill-health (dated Sept. 30th, 1908).

Captain E. T. Inkson, V.C., from London, is appointed for duty in India.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Joseph Adams to be Surgeon-Lieutenant-Colonel (dated Sept. 22nd, 1908).

TERRITORIAL FORCE.

Yeomanry.

Buckinghamshire (Royal Bucks Hussars): The undermentioned officers from the Buckinghamshire (Royal Bucks Hussars) Imperial Yeomanry are appointed to the regiment with rank and precedence as in the Imperial Yeomanry (dated April 1st, 1908): Surgeon-Captain Leonard Arthur Barwell and Surgeon-Captain Francis Ernest Marston. Queen's Own Oxfordshire Hussars: Surgeon-Lieutenant Archibald Henry Hogarth, from the Oxfordshire (Queen's Own Oxfordshire Hussars) Imperial Yeomanry, to be Surgeon-Lieutenant, with precedence as in the Imperial Yeomanry (dated April 1st, 1908).

Royal Field Artillery.

2nd South Midland Brigade: The undermentioned officers from the 1st Worcestershire Royal Garrison Artillery (Volunteers) are appointed to the brigade, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain Arthur Charles Oldham, Surgeon-Captain George Herbert Rutter, and Surgeon-Lieutenant George Mackie (to be supernumerary).

Royal Garrison Artillery.

Devonshire: The undermentioned officers, from the 2nd Devonshire Royal Garrison Artillery (Volunteers), are appointed to the unit, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain James Philip Stephens Ward and Surgeon-Lieutenant George Douglas Kettlewell.

Infantry.

4th Battalion, Cheshire Regiment: The undermentioned officers, from the 1st Volunteer Battalion, The Cheshire Regiment, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Conrad Theodore Green, Surgeon-Captain John Brown Yeoman, and Surgeon-Captain Andrew Robertson Wilson (to be supernumerary). The undermentioned officers from the 3rd Glamorgan Volunteer Rifle Corps, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Major Arthur Lloyd Jones, Surgeon-Captain George Arbour Stephens, and Surgeon-Lieutenant Charles Leonard Isaac (to be supernumerary). 7th (Fife) Battalion, The Black Watch: The undermentioned officer, from the 6th (Fifeshire) Volunteer Battalion, The Black Watch (Royal Highlanders) is appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Lieutenant David Elliot Dickson. 5th Battalion, Loyal North Lancashire Regiment: The undermentioned officer, from the 2nd Volunteer Battalion, The Loyal North Lancashire Regiment, is appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain James Wood. The Herefordshire Battalion, The King's (Shropshire Light Infantry): The undermentioned officers from the 1st Herefordshire Volunteer Rifle Corps, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain James Neil Macmullan and Surgeon-Lieutenant Arthur Llewellyn Baldwin Green. 6th (Banff and Donside) Battalion, Gordon Highlanders: Surgeon-Lieutenant Ellington Reed Turner from the 4th (Donside Highland) Volunteer Battalion, The Gordon Highlanders, is appointed Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). 5th (Renfrewshire) Battalion, Argyll and Sutherland Highlanders: Surgeon-Captain Claude William Marshall, from the 1st (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 6th (Renfrewshire) Battalion, Argyll and Sutherland Highlanders: Surgeon-Captain Wallace Ainsforth Pride, from the 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 7th Battalion, Argyll and Sutherland Highlanders: Surgeon-Lieutenant Peter McFadyen, from the 4th (Stirlingshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders), to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). 9th (The Dumbartonshire) Battalion, Argyll and Sutherland Highlanders: Surgeon-Captain William Buchan Armstrong, from the 1st Dumbartonshire Volunteer Rifle Corps, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Correspondence.

"Audi alteram partem."

THE PREVENTION OF TUBERCULOSIS (IRELAND) BILL.

To the Editor of THE LANCET.

SIR,—It is satisfactory to find that Dr. J. C. McWalter's opposition to the Prevention of Tuberculosis (Ireland) Bill is lessening, for in his letter in your issue of Oct. 3rd, p. 1035, he says: "Everyone could see that compulsory notification may be an excellent thing in a city where a whole population works together in crowded factories and a doubtful experiment for a whole country where the conditions are absolutely different." Now, if Dr. McWalter had shown that phthisis occurred only in such cities and not in other places there would be some weight in his opinion. For instance, Belfast is, practically speaking, the only big city in Ireland where a large number of the population work in large factories, and on Dr. McWalter's reasoning compulsory notification should apply to that city alone in Ireland; but unfortunately in both Cork and in Dublin the death-rate from phthisis is higher than in Belfast; and, further, in every other city in Ireland—nay, more, in every district in Ireland—this fell scourge has its victims. During 1907 of the 8828 deaths from phthisis (tuberculous phthisis and phthisis not otherwise defined) 2596 occurred in Leinster, 2178 in Munster, 3100 in Ulster, and 954 in Connaught—that is, in every part of Ireland, urban and rural. Now of these, 1054 occurred in Belfast; yet that city alone with only 1054 deaths is to be under compulsory notification (according to Dr. McWalter's plan), while the whole of the rest of Ireland with 7774 deaths is not. Such a line of reasoning carries its own reply. Dr. McWalter says the example of an odd city goes for nothing, he wants me to point out an entire country where compulsory notification prevails and causes no hardship. The cities I enumerated were Sheffield, Bolton, Edinburgh, and New York, and their united population is 3,335,314—that is, only about 1,000,000 less than the population of the whole of Ireland. In each of these cities the phthisis death-rate had steadily fallen before they adopted compulsory notification, but not content they are determined it shall fall still more, and yet, sad to say, during all this period the death-rate from tuberculosis has risen in Ireland. If the compulsory notification of the disease is adopted it must apply to every part of Ireland (urban or rural) until the disease is stamped out.

As to a country where notification is adopted: 1. Let me give, if not a country, what is practically the same, a great state of a country. New York State is larger than England, it has a population little less than twice that of Ireland—viz., about 8,000,000—and in it the notification of even incipient cases of tuberculosis is rendered obligatory; the same is true of New Jersey and the District of Columbia. Compulsory notification will soon exist in the whole of the United States. 2. On Sept. 28th, 1908, at the International Congress on Tuberculosis in Washington, Dr. A. Newsholme stated, on behalf of Mr. Burns, that the *Local* Government Board had decided to issue an order compelling all Poor-law medical officers to notify forthwith the medical officers of health of any sanitary authorities making application for such notification, all cases of phthisis occurring amongst parochial patients. This order would also render it obligatory on other Poor-law officials to and modern observations in regard to our knowledge of the marvellous solar system. The book, of course, offers very little material which can usefully be discussed in a medical journal but it is needless to remark that the subject offers most interesting reading to the possessors of the scientific mind. The author has entered into a rather full discussion of recent writings concerning the existence of the canals in Mars. Certain highly imaginative and exceedingly popular ideas in regard to this planet have, he says, obtained such prominence and are supported with such a mass of apparently valid observations that they cannot be dismissed with a word. In 1877 the Italian observer, Schiaparelli, found on the continents of Mars a number of straight dark lines which he called *canali*. For many years the reality of this discovery was doubted but about ten years later the existence of some of these markings was confirmed and astronomers have since observed these channels. The tendency, however, of modern views is in the direction of incredulity.

THE ARMY MEDICAL REPORT FOR 1907.

THE Army Medical Report for 1907 has been issued and certain of its features are noticed in a leading article on p. 1026 of our present issue. It contains other noteworthy details, prominent amongst which is the section dealing with malarial disease, which, it is satisfactory to note, has decreased in India, although its prevalence during the year 1907, as indicated by the admission ratio per 1000 of strength, exceeded that of the year 1905, the numbers being for 1905, 111·9; 1906, 179·5; and for 1907, 153·8. Under the head of enteric fever in India the report states "that the usual seasonal prevalence in the spring and autumn was much less marked, the cases being more evenly distributed throughout the year." The investigations carried on at the Central Research Institute at Kasauli as to the part played by "bacillus carriers" in spreading the disease agree with the results obtained by Koch and others in Europe. As it has been shown that the discharge of bacilli is intermittent, intervals of 80 days occurring, and that in convalescents it persists for several months, sometimes many years, and that in Germany one authority asserts that 1·5 per cent. of the general population are "carriers," the report urges "that where dozens of cases occur daily ...... to detect all slight cases of enteric, to examine and repeatedly examine the excreta of convalescent and suspected carriers, plus persons handling food in kitchens, institutions, bakeries, dairies, sweet manufactories, &c., &c., while an ideal to be aimed at, is at present as impracticable in the prophylaxis of typhoid, as it is in the case of diphtheria, influenza, pneumococcus, *meningococcus*, or cholera 'carriers.'"

The result of rigid sanitary precautions in the garrison of Bermuda was rewarded by the very light list of only 14 cases of enteric fever, including women and children, notwithstanding an exceptionally heavy outbreak of the disease among the civil population. The insanitary conditions in the town of Hamilton and the endemic prevalence of the disease, sometimes in so mild a form as to render accurate diagnosis difficult, if not impossible, and the constant influx of visitors from the American continent, many of whom may well be typhoid carriers, add to the responsibility and difficulty of the sanitary authorities in dealing with this disease. Valuable scientific work is being carried out in the bacteriological laboratory at Pretoria with a view of determining what proportion of enteric fever occurring in South Africa is due to bacillus typhosus. So far it has been found that out of 35 strains of the typhoid bacillus group, isolated from various sources, 20 per cent. of the total were atypical, including one case of bacillus coli communis.

The report shows the actual deaths from pulmonary tuberculosis to be extremely few in the military service as compared with the male civil population. It is, however, justly pointed out that regard must be had to the invaliding figures, and it should be borne in mind that the ratio represents only young male adults living, for the most part, under favourable sanitary conditions, and who but recently, after careful medical examination, showed no trace of the disease, which it seems is not unfrequently latent under apparently [illegible]nditions.

Investigations into an epidemic of sore-throat at the Duke of York's School showed that the disease was non-diphtherial in type among the boys, while in the cases of attendants, washerwomen, and so on, pseudo-diphtheria bacilli were found, and in two instances of persons indirectly associated with the school the throat swabs gave pure cultures of diphtheria bacilli. These facts may explain why in cases diagnosed as diphtheria severe symptoms have been followed by prolonged convalescence and frequent occurrence of paralysis. In some cases recovery has been quick and uninterrupted; in others symptoms of rheumatism have almost invariably succeeded.

It is curious to note that the death-rate from diseases of the digestive organs is above that of civil life, but it must be noted that cases of hepatitis and liver abscess, probably contracted in the tropics, are included. It is suggested that less stress is now laid on dental caries as a reason for invaliding and that the routine dental examination is not being followed up.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Oct. 9th, 1830.

AMPUTATION OF THE LEG AT THE KNEE-JOINT.

AT the sitting of the Académie des Sciences on the 13th of September, M. Velpeau, of the Hôpital St. Antoine, read a paper on the above operation, which, according to him, is not so dangerous as is generally believed, and ought even to be preferred to ordinary amputation, where the joint is healthy. He has himself performed it twice with complete success, once in January, 1830, on a young man affected with necrosis of the tibia, part of which it was M. Velpeau's intention to remove, when he found, after having made a transverse incision, that the bone was throughout diseased, so that it was necessary either to perform the amputation of the thigh, or the exarticulation of the leg; he preferred the latter, as, in fact, a part of it was already performed by the transverse incision. The operation did not afford any-thing of interest; the wound speedily healed, and the patient was quite well after eight weeks. The second case was that of a robust man, 29 years of age, with fracture of the left leg: when he was brought into the hospital, twenty-four hours after the accident, considerable hæmorrhage had taken place, and almost the whole of the limb was covered with ecchymosis; the fracture appeared, however, simple, and there was but a small wound at the inner ancle, and scarcely any swelling. The limb was carefully dressed, and a favourable result of the case was anticipated, when, on the following night, the patient was suddenly seized with furious delirium, the cause of which could not be ascertained until the fifth day, when it was discovered that mortification began to take place, and three incisions having been made over the fracture, the tibia was found to be minutely fractured, and its fragments surrounded by a gelatinous mass of very offensive smell. Profuse suppuration of an unhealthy kind ensued, accompanied by excruciating pain and hectic fever, so that the removal of the limb did not admit of any longer delay. The success of the above case determined M. Velpeau to perform the exarticulation of the leg at the knee-joint, as amputation below it was inadmissible. The operation took place on the 4th of June, and the patient was perfectly cured on the sixtieth day. The third case which had come under M. Velpeau's observation, was that of a young man whom he happened to examine at the Bureau Central, and who in his twelfth year had undergone the operation at the Hôpital des Enfans, on account of gangrene. From these instances, and others related by medical writers, M. Velpeau concludes, that exarticulation of the leg ought not to be entirely excluded from the index of surgical operations, as it has hitherto been done by most modern writers on surgery.

QUACKERY.—"In the year 1782, that extraordinary empiric of modern days, Dr. Graham, appeared in London. Among the furniture of Dr. Graham's temple was a celestial bed, which, he pretended, wrought miraculous effects on those who reposed in it; he demanded for its use during one night, one hundred pounds, and such is the folly of wealth that several personages of high rank acceded to his terms."—*Hone's Table Book.*

of establishment and upkeep, will be ten millions a year; and then if a local authority wish to build a sanatorium they are faced with the express declaration of Dr. Cox's College of Physicians—that it is an extravagant and impossible outlay for a country like this.

The only real effect of the Bill will be to drive patients from the physician to the quack. There will be compulsion on the doctor to notify every consumptive who comes before him, but none on the consumptive to go to the doctor; he can roam at large and go where he will, spreading contagion as heretofore, impossible to check as long as he avoids the physician. The latter may indeed be called in at the end, but only when curative or preventive measures are alike futile. If it is granted, then, that compulsory notification can only do practical good when all cases of phthisis are notified, what percentage of people will present themselves for notification in a country where already nearly a quarter of the people die without calling in the doctor?

I am, Sir, yours faithfully,

Dublin, Oct. 4th, 1908. J. C. McWALTER.

THE FEEDING OF ELEMENTARY SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—The beginning of the provision of meals for school children has, of course, opened the question of methods to be used in selection. The public and many of its committees, accustomed to hearing evidence given by medical men on the subject of starvation and looking also to the profession to dogmatise on all aspects of dietetics, have erroneously assumed that by inspection and examination of children the medical man is able to say that one child should be fed by the ratepayers whilst another may be left to the care of its parents. Anyone with experience must be aware that this is a mistaken conclusion. Starvation may, of course, be recognised, but what is wanted in the case of the children is the recognition of *underfeeding* which may perhaps have continued only for a week or so. In the majority of cases such a diagnosis is absolutely impossible.

Weighing and measuring, however useful in providing evidence of "tendencies," give practically no certain information as to the individual. The average healthy child seems to have an extraordinary vitality and may be *underfed*, I do not say *starved*, for long periods and yet remain apparently in excellent health, though it is probable that its future growth is being injuriously influenced. If measurements and appearances are not to be relied on, by what is the diagnosis to be made? Even in cases where it is obvious that the tissues of the child are not being sufficiently nourished it is always possible that the absorption from the digestive tract or metabolism is at fault. We have all seen cases of children from good homes who if dirty and dressed in rags would at first sight have been considered as insufficiently fed.

Leaving aside such cases where the appearance makes it obvious that something is wrong either with the child or its feeding there remain the underfed children of whom I first spoke; these, healthy in appearance, cannot be recognised with certainty by anyone as being insufficiently fed. It is possible to point out cases that should be fed but it is not possible for the medical man on inspection and examination to affirm that children are not underfed. The only possible method, if selection is to be exercised and mistakes are to be avoided, is that of visiting the homes and acquiring information there. Of course, I do not suggest that the doctor should do this.

My reason for writing this letter of truisms is that already in places where the medical men are helping in this work—and it is certain they should help—there is a tendency to leave the decision on the question of feeding individual children entirely in the doctor's hands. If he reports that "there is no evidence on examination that the child A. B. is underfed" it is immediately concluded that he means that the child is sufficiently fed at the time of examination, a statement which no medical man would think of making without further information than inspection affords. The fallacy has arisen in the lay mind from the confusion of "starvation," which is recognisable, with "underfeeding," of which it is very difficult to be certain. It seems to me important that we should make it clear that we cannot be sole judges in this matter in all cases.

I am, Sir, yours faithfully,

Blackburn, Sept. 29th, 1908. MILES B. ARNOLD.

CANTHARIDES POISONING.

To the Editor of THE LANCET.

SIR,—Since communicating with you recently re a case of acute cantharides poisoning in an adult,[1] a second case of a very similar nature has come under my notice and I venture therefore to record these few additional facts.

The patient, an Austrian subject, was admitted to one of the private wards of Johannesburg Hospital on July 26th, under the care of Dr. H. B. Currie, giving a history as follows. He was taken ill on Saturday, July 18th, with (1) stabbing pain in the left side just at the costal margin, and (2) pain in the knee-joint (right). On the 24th he developed a cough, which was associated with scanty mucopurulent expectoration of a greenish tint, whilst the pain previously in existence became intensified and shortness of breath on exertion was experienced. Accordingly, he consulted a practitioner in town who advised the application of a blister. At 8 A.M. on the 25th a piece of plaster (emplastrum cantharidis B.P.), measuring 5½ inches by 4½ inches, was applied to the chest wall below and to the outer side of the left nipple. 13 hours afterwards (at 9 P.M.) the first symptoms appeared. The patient states that he felt a desire to pass urine every hour or so and could not keep (i.e., retain) it for a longer period. Pain was experienced at the end of the penis when the act was nearing completion; the urine voided was the colour of beetroot water. Headache developed in conjunction with the other symptoms, but there was neither vomiting nor purging; indeed, it appears that for the first 48 hours the bowels remained inactive.

On admission, on Sunday, July 26th, the physical signs indicative of disease were those of pleurisy with effusion on the left side. There was a raw surface measuring 5½ inches by 4½ inches below and to the outer surface of the nipple. The temperature was 102° F., pulse 106, and respirations 39 per minute. The patient's tongue was heavily coated. His bowels had not been opened since the 24th. The right border of the heart extended a finger's breadth beyond the edge of the sternum; the apex beat was well defined, being visible in the fifth left interspace at a point one inch internal to the nipple line (very little displacement noted). The first and second sounds were clear at the apex and there was no suspicion of a murmur. The belly wall was not rigid and there was a complete absence of abdominal pain and tenderness. The patient apparently did *not* experience pain in the region of the kidneys. There was no undue frequency of micturition though a good deal of pain of a burning nature was present just within the orifice of the urethra towards the end of the act of micturition. The urine was loaded with amorphous urates and red cells and yielded after careful filtration a well-defined cloud of albumin. The specific gravity of the filtered urine was 1028, and it was acid in its reaction to litmus paper. A subsequent analysis made on July 28th yielded results as follows: Specific gravity of filtered urine, 1027; reaction of filtered urine, acid; fairly dense cloud of albumin precipitated on warming the solution; centrifugalised deposit found to consist of amorphous urates, leucocytes, red blood cells, granular casts, and a few kidney cells. A third analysis carried out on the 30th demonstrated the existence of numerous kidney cells. The specimen of urine selected for examination proved turbid from precipitation of mucus and urates but cleared up on gently warming. Its specific gravity was 1022 and reaction was acid as on previous occasions. The centrifugalised sediment yielded one or two red blood corpuscles, a fair sprinkling of leucocytes, several short granular and hyaline casts, a few epithelial cells from the urinary passages, and quite a number of renal epithelial cells with coarsely granular protoplasm, scattered and in groups of from 20 to 30 or more. On August 1st the chief change noted was a diminution in the number of formed elements. Beyond a few truncated granular casts and kidney cells all in an advanced stage of degeneration there physician, he being asked to report on pathological products often without any information being given to him of the clinical details. Dr. SLATER suggested that the clinical pathologist and the physician should consult together by the bedside on equal terms and that the conclusions arrived at should be the joint result of their deliberations. The development of medicine as a science was the theme of the address given by Dr. A. M. KELLAS at the Middlesex Hospital, and he traced the chief theories of disease from early times to the present day. He then dealt with the relation of chemistry to medicine and showed that a full comprehension of the physiology of the body cannot be obtained until we know the composition of proteins and other obscure organic bodies, and he pointed out that with regard to pathology this knowledge is equally important. He mentioned the enormous numbers of atoms entering into these complex molecules, and emphasised the fact that our lack of knowledge of the true chemistry of the body is delaying the progress of medicine. Real progress in these difficult subjects could best be made by the adequate endowment of several professorships, and for this only a moderate sum would be needed whilst the results would fully compensate for the cost incurred. Dr. HARRINGTON SAINSBURY, at the London School of Medicine for Women, spoke of the importance of the individual cell in both medicine and surgery. Surgery is yearly extending its bounds and claiming more and more of the grosser structure of the body, but the cell, its powers, and its potentialities must ever remain the realm of the physician, for the individual cell is beyond the claim of the surgeon. Yet even in surgery the cell plays an essential part. In vain will the fragments of a broken bone be placed together if the osteoplastic cell be not ready to exert its powers; the tying of a cut artery is useless if the plastic properties of the cell are not employed to close the vessel. Further, he urged the importance of not over-valuing the drug treatment of disease, though he claimed for drugs that the powers which they do possess should be recognised. The public look upon a prescription as the essential part of treatment, but the true physician must recognise the importance of other methods of healing, and amongst these the influence of the mind must not be forgotten. Dr. SAINSBURY concluded his address by urging the need of cultivating all the powers of the mind, for in the study of medicine there is no small risk that the student may neglect all that stands outside the medical curriculum. The student should acquire and maintain an interest in poetry, in art, or in music, to consider only the æsthetic side of the mind, but in addition the student must not forget that the ethical and the religious aspects of humanity need also consideration and culture, for they are of even more importance than the æsthetic. All these mental potentialities need culture for their growth, for they will atrophy if they are disused.

---

[1] See THE LANCET, Sept. 12th, 1908, p. 800.

From these glances at some of the opening addresses at the medical schools it can be seen that the lecturers all appreciate the dignity and importance of medical studies, they suggest the lines along which progress must go, they urge the need of due attention to the claims of science, and they point to the rich reward to humanity which follows the teaching and practice of medicine. At most of these addresses eminent laymen were present and we hope that they laid to heart the teaching which they there heard and that they are in consequence more alive to the economic importance of medicine. That the new students will remember all the valuable advice poured forth at these addresses is too much to expect, but at least it may be hoped that they were influenced for good and that they will study their profession the better for hearing of the high ideals which have been placed before them.

The Professional Status of Anæsthetists.

RECENT discussions which have arisen have associated the ever-present question of how to prevent deaths occurring during anæsthesia with the present position of those members of our profession who have adopted the specialty of administering anæsthetics. Dr. F. W. HEWITT, physician-anæsthetist to St. George's Hospital, stated at the meeting in Dublin of the British Association for the Advancement of Science views practically identical with those which he advanced some weeks back at the Medico-Legal Society. His paper was published in THE LANCET of Sept. 19th, p. 873, and from this it will be seen that his contention is that deaths from anæsthetics are in some cases due to want of skill or experience on the part of those who give them, and he pleads for a legal enactment which shall limit the practice of giving anæsthetics to those who possess medical diplomas. But it is rightly pointed out that even this safeguard is not sufficient since there are many of the qualifying bodies which grant degrees or diplomas enabling the holders to practise, but which do not insist upon candidates for their qualifications producing evidence of even a modicum of knowledge of the action and uses of anæsthetics. To remedy this serious blot upon our scheme of medical education it would be necessary for the General Medical Council to advise the Privy Council to insist that all qualifying bodies should fall into line with the English Colleges and should require everyone seeking to practise to show his competence, by examination or otherwise, to administer anæsthetics. We concur in hoping that some such step will be taken in the near future.

There is some reason to believe that the medical student of to-day is influenced by the appraisement set by the controlling powers upon the bewildering number of subjects which he is expected to master during his hospital course. Anæsthetics have less allurement than let us say bacteriology, and examinations of the dark passages of the human frame offer more interest to the beginner than acquiring a perfunctory acquaintance with the processes of narcosis. So that when, as is alleged, the hospital authorities belittle the importance of anæsthetics as a part of the curriculum, the students, not slow to avail themselves of the opportunity offered to them to lighten the burden which they perforce must bear, leave anæsthetics severely alone. The writer of a letter in the *Times* who adopts the *sobriquet* of "A Hospital Anæsthetist" tells us that hospitals are sometimes badly equipped in the department of anæsthetics, and that the men who undertake the duties of anæsthetists to hospitals and of teaching students are often juniors who regard think tends to show that Mark was actually the author of the Gospel which bears his name.

Oct. 6th, 1908. I am, Sir, yours faithfully,

A PHYSICIAN.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—I have been much struck by the one-sided view you take of the question of an M.D. degree for London students. I think that graduates of the University of London should have something to say on this subject. I may be writing from a purely selfish point of view, but I am certain that I am giving the opinion of many fellow graduates. The M.D. London was looked upon both by the profession and the laity as the hall-mark of medicine. Why strive to lower it? If everyone can obtain it what value will it have and what recompense can be given to the unfortunate men who worked so hard in the old days to obtain it? As it is, the standard has already been lowered quite enough. If everyone obtains the M.D. London will there be left any higher honour for students to strive after? Surely ambition is of some value, and it does not appear likely that everyone will be content to remain on a dead level. Surgeons would not be pleased if the F.R.C.S. was made accessible to everyone. And after all, is the M.R.C.S., L.R.C.P. a qualification to be ashamed of? Surely it is of more value than many a Scotch or Irish degree. To illustrate the grievances which alterations of this kind cause, I may mention a point which does not appear to have been touched upon previously—namely, that formerly one had to pass a separate examination for the B.S. London, whereas now the degree is styled M.B., B.S., so that although formerly M.B., B.S. stood for two separate examinations, the B.S. being for a higher examination in surgery, now the letters only signify the ordinary pass examination. Therefore the time and trouble spent over the old B.S. degree now counts for nothing.

In conclusion, Sir, if everyone wishes to be styled "Doctor" there is no objection, but do not lower the standard of the University of London examinations to allow them to obtain this title.

I am, Sir, yours faithfully,

M.B., B.S. LONDON.

THE SECOND CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY AT BRUSSELS.

(FROM OUR SPECIAL CORRESPONDENTS.)

(*Continued from p. 1037.*)

Acute Angiocholitis.

ON the second day of this Congress Professor QUÉNU and Dr. DUVAL (Paris) made a communication upon Acute Angiocholitis, which they said was always due to microbic infection, the microbes reaching the liver either by the bile ducts or by the hepatic artery and portal vein. Infection along the vascular system was, however, more common in the primary forms due to pneumococci, influenza, and cholera, whilst secondary angiocholitis was associated with gall-stones, the penetration of foreign bodies into the bile ducts, and pregnancy. Angiocholitis also occurred in the course of piles and of appendicitis. Treatment consisted in operation, during the quiet stage if possible, drainage of the bile ducts and gall-bladder following upon cholecystotomy.

Cancer.

The meeting then resumed the discussion on Cancer, and Professor CZERNY, the President, presented his report upon Cancer of the Œsophagus and Stomach, Liver, Biliary Ducts, Pancreas, and Peritoneum. He thought that cancer of the œsophagus should be operated upon whilst it was still localised and he preferred operation to the use of bougies. Carcinoma of the gall-bladder was so often secondary to gall-stones that especial care should be taken to recognise and to treat them early. Cancerous peritonitis was nearly always secondary to cancer of a neighbouring organ, though the primary lesion might be difficult to discover even at the necropsy. The treatment of cancer of the stomach, as was well known, had proved very satisfactory, and Professor Czerny advocated a better selection of cases rather than more extensive operation. Cancer of the pancreas, he thought, was extremely difficult to recognise during life, and although the organ might be removed in part he considered palliative measures to be the more satisfactory,

Mr. D'ARCY POWER (London) brought forward a case of Primary Malignant Disease of the Spleen. He showed the specimen, which weighed 66 ounces. The patient was a woman, aged 47 years, who died six months after the operation. He stated that the case was the twelfth of which a record existed. All the cases were sarcomatous. Splenectom was performed; five cases recovered and seven were cured.

Abscess of the Liver.

Reports on Abscess of the Liver were presented by D LEGRAND (Alexandria) and by Dr. VORONOFF (Cairo) They considered that alcoholism was a factor in producing a tendency to amœbic or pyogenic infection and agreed tha an operation ought to be performed as soon as pus was recognised. Plugging was the only way of arresting hæmorrhage during operation and no reliance should be placed upon the thermocautery or forcipressure when dealing with bleeding from the liver.

Professor PAYR (Greifswald) pointed out that much was still required to complete the diagnosis of tumours of the liver. He thought that the severe pain which often accompanied simple tumours of the liver and the tendency towards their association with malignant disease justified early surgical interference in all cases where they could be recognised.

Anæsthesia.

Reports on anæsthesia were presented by Professor VALLAS (Lyons), Dr. LOTHEISSEN (Vienna), Professor REVERDIN and Dr. BERGALONNE (Geneva), Dr. ROUFFART and Dr. WALRAVENS (Brussels), Professor REHN (Frankfort), Dr. ZAHRADNICKY (Bohemia), Dr. MOTY (Paris), Dr. MACARTHUR, and Dr. ALEXIUS VON HINTZ (Maresvasarhely).

Surgery of the Spinal Cord.

Professor F. DE QUERVAIN (La Chaux-de-Fonds) introduced a discussion on Injuries of the Spine and Spinal Cord. In his paper he pointed out that there were no definite signs of spinal concussion, that was a functional disturbance without any anatomical lesion. When a case of spinal injury could be examined at once it was generally possible to distinguish between a partial and a total lesion of the cord, but later it might not be possible. When the tendon reflexes were present it was practically certain that a total lesion of the cord was not present, but the converse of this proposition was not always true. The nervous symptoms present did not enable a diagnosis to be made between compression and contusion of the spinal cord. From experiments on dogs and rabbits there was no probability of success in suturing the spinal cord. Neither extradural nor intradural hæmorrhage of the spinal cord was an indication for operation, except perhaps when a hæmatoma of the cervical cord was causing interference with respiration, but the diagnosis would be very difficult. When a diagnosis of hæmatomyelia was made an operation should be performed. An operation was also indicated when the diagnosis suggested that the symptoms present were due to fracture of the laminæ of a vertebra or when a skiagram showed that a bullet was in the neural canal. An operation was advisable, though the chances of success were small, when an irreducible fracture-dislocation was present, or when a splinter of bone was compressing the cord. At present an operation in a total transverse section was looked upon as useless, but if the reported successful case was confirmed by the work of others then an operation would be clearly indicated in nearly all such cases. Dr. de Quervain had collected 218 cases of operation for injury of the spine and cord, with the result that recovery followed in 13·8 per cent., and of these in 10·5 per cent. the improvement was certainly influenced by the operation; 22 per cent. were improved; in 37·2 per cent. no obvious change was present, in 1·8 per cent. the operation appeared to do harm, and in 25·2 per cent. the patient died.

Professor BERARD (Leipsic) reported on Tumours of the Spinal Cord and urged that in doubtful cases there should always be a consultation between the physician and the amounted to over 208 per 1000 of the strength of the force employed in the London district. Such an amount of infection reveals a state of affairs not only deplorable in itself but fraught with danger to the public health, unfortunately not only of this but of future generations, a danger for the mitigation or stamping out of which, in the present state of public opinion, it seems hopeless to look to legislation. The death-rate and invaliding rate from diseases of the heart and circulatory system are high and afford abundant material for study and investigation. It is said, and fairly strong evidence is brought forward to support the dictum, that a soldier of 30 is "at least five years older than a civilian of the same age," and this sudden passing of the soldier into middle age is due to circulatory troubles, but the numerous exceptions to such a generalisation and the fact that the officer class are not affected in the same way would seem to indicate that the admittedly unsatisfactory state of things arises from causes which are capable of being brought under control. We are inclined to believe that a series of causes *acting together* are often responsible: syphilis, alcohol, tobacco, malarial infection, with climatic changes and altered conditions of blood pressure. "As regards the relative importance of the different causes of invaliding, diseases of the circulatory system still hold the first place," as they have done, with one exception, for the past 27 years. While disordered action of the heart in immature recruits may be sometimes entirely functional in its nature "as from a dilated stomach," in which case they ought not to be invalided but detected and cured, we must reiterate the conclusion which we have recently on several occasions expressed in these columns, that, as a rule, it is due to different forms and degrees of cardiac dilatation, which, apart from any valvular defects, leads to regurgitation at the auriculo-ventricular orifice. It would be interesting if we could obtain from the medical records of civil life some data as to the prevalence of diseases of the heart and circulatory system amongst those constantly engaged in arduous labour, as in lifting and removing articles of heavy furniture. We are inclined to surmise that in the case of the soldier it is the intermittent nature of the heavy work, at any rate in the case of persons with fairly sound arteries, that does the mischief.

During the past year important changes were introduced in the scale of rations for foreign stations, which were brought into more uniformity as regards grocery and vegetable rations, the scale adopted being per diem: tea, ⅝ ounce, or coffee, 1¼ ounces; sugar, 2 ounces; salt, ½ ounce; pepper, 1-36th ounce; fresh vegetables, ½ pound, or dried vegetables, 2 ounces, and this must be considered together with the purchase value of the messing allowance granted to each soldier. The meals are now served to the mess collectively in rooms and dining halls specially set apart for the purpose, which allows of a greater variety in foods and obviates the dirty and unhealthy practice of using the men's dormitories for meals. Steady, if slow, improvement is reported in the comfort of barrack buildings from year to year. Reconstruction and remodelling of the drainage systems have been widely proposed and in some instances inaugurated, soldiers' married quarters have been improved and extended, the water-supply has been dealt with, lavatory accommodation increased, and plunge- and shower-baths erected, and the gravity of the question of sewage disposal has been recognised. Should the hygiene and sanitation of our army ever attain the standard now indicated the result will more than reward and justify the care and expense. The present state of affairs is a matter of gratification, at least when compared with that revealed half a century ago after the Crimean war. We must briefly notice, however, a section of the report which appears to us both gloomy and unsatisfactory: this deals with the all-important subject of recruiting, touching essentially and, as we have on several recent occasions emphasised in these columns, indicating the grave problem of the health and physique of the young adult male population. Last year, roughly speaking, nearly 300 per 1000 recruits were either rejected on inspection or found unfit within three months of enlistment. Notwithstanding that a fixed standard of weight has been abolished, that the medical examiners have passed all who came up to the physical requirements of infantry of the line, although they were afterwards rejected by the recruiting officer because they were too small for the corps of their choice, that "a more lenient standard of dentition" has been adopted, "that varicocele is viewed with greater leniency now than in past times," and that men are now accepted "with only one-sixth of the normal acuteness of vision in one eye, provided that the other is normal," "the majority of recruits were growing lads ...... 95 per cent. of the total out of work at the time of enlistment ...... in many instances suffering from want of food ...... most of the men will not be capable of doing the work of a mature soldier for at least two years. ...... Immaturity has always been the outstanding defect of our recruits, and in this respect little or no improvement was shown during the year." Both under the head of recruiting and invaliding the unsatisfactory result of employment of inexperienced medical men is alluded to. It is impossible to exaggerate the importance of these points, being, as they are indeed, the finger on the pulse of the national health. Recent investigations have given an uncertain answer to the question whether the national health was improving or deteriorating. We should like to see a small practical committee appointed which would make up its mind and give us a definite opinion on this point. Practical experienced medical men and employers of labour could tell us more real truth on this subject than philanthropists, statesmen, and men of science, with their own axes to grind and their own theories to establish at the expense of facts.

Annotations.

"Ne quid nimis."

RECENT CHANGES IN THE NAVY.

WE are glad to notice that the new medical director-general of the navy has lost no time in strengthening the Haslar course. During the last session the examination of recruits, the administration of anæsthetics, and other subjects coming within the sphere of a naval surgeon's duties have been systematically taught. We observe with pleasure that on the whole the recent changes in the victualling of the navy have been attended anæsthesia, whilst the mid-European nations employ intraspinal and local anæsthesia to a much greater extent than is usual in Great Britain. The discussion on diseases of the spinal cord was not productive of anything new. The discussion on hernia produced a number of interesting reports amongst which not the least interesting was that by Dr. W. Sheen of Cardiff upon hernia in relation to the Employers' Liability Act. He states that true traumatic hernia is of rare occurrence and is usually strangulated. The more usual form occurs with a gradual and painless onset, though the rupture may first be noticed at work during a lifting effort.

The meeting suffered from a wealth of material. There were more members anxious to speak than time would permit and some were disappointed. The international committee has recognised this grievance and at the next meeting there will only be three subjects for discussion instead of five as at the present meeting.

It will be seen that every one of the questions discussed was on a matter of great surgical interest, but the mistake is nearly always made in congresses such as these of having too wide a subject for discussion, for if the question is extensive the remarks of subsequent speakers do not deal with the same points and the utility of the discussion is greatly diminished. This is a danger that should be guarded against, for it leads to fruitless meetings. The Congress at Brussels was very happy in the choice of subjects and some advance in surgical opinion should result.

THE SANITARY DEFENCE OF THE HEDJAZ RAILWAY.

(By the British Delegate on the Constantinople Board of Health.)

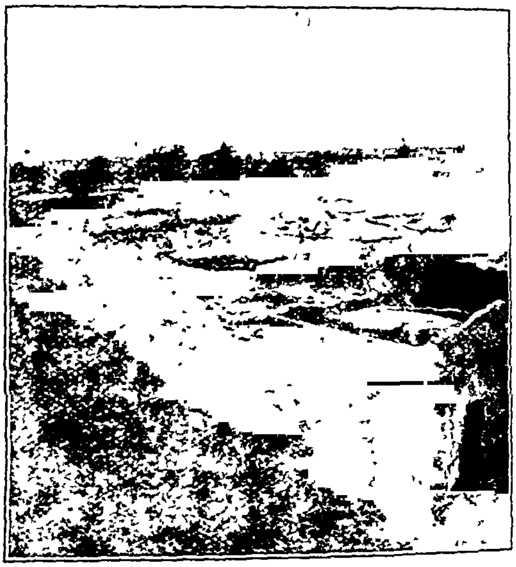
(*Illustrated with Reproductions of Photographs taken by the Author.*)

II.[1]—Tebuk.

From Ma'an the Commission went on to Tebuk, about 11 hours distant by railway. Most of this portion of the journey was done by night, so that I can say little of the country lying between the two, but shortly after leaving Ma'an the line passed through a very remarkable bit of scenery. The flat or undulating desert suddenly comes to an end on the brink of a steep descent and here the line, by a series of curves, passes through a gorge or ravine known to the Arabs as the Batn-el-Ghoul, literally the "Belly of the Fiend." The sandstone rocks are of rather fantastic shapes, though much less so than in the gorge leading to Medaini-Salih, to be mentioned later. But their colour is extraordinary; I should rather say colours, for they are striped and blotched in patches of reds, browns, yellows, purple, even green, and almost white, giving a curiously weird aspect to the landscape, particularly as seen at sunset.

Tebuk is situated at the 692nd kilometre from Damascus and consequently is 610 kilometres north of Medina. It lies at a height of 775·3 metres (say 2500 feet) above sea level. The village is about half a mile away from the station in the midst of a highly picturesque oasis of palm trees, figs, and pomegranates. The station is an important administrative centre on the railway. Moreover, Tebuk has always been a place of some consequence on the Pilgrims' Way, as it was here that the Beni Attiyeh, the largest bedouin tribe in this region, were paid their toll-money to allow the passage of the pilgrims. The Commission, for reasons to be discussed later, decided definitely that Tebuk will be the most suitable place in which to establish the permanent lazaret for pilgrims returning from the Hedjaz, and for this reason I propose to describe in some detail the local conditions, more particularly from the point of view of their suitability (or the reverse) for the establishment of such a lazaret. The village occupies a position slightly raised above the general level, but for many miles round the desert is an almost flat expanse; the sandy and gravelly surface shows only slight irregularities, which would offer no difficulties for building purposes. The site recommended for the future lazaret lies to the south of the village and the west of the line. This site would be limited on the north by the railway hospital and on the east by the line, and in the other directions would be practically unlimited. In the neighbourhood is a large quarry of excellent building stone: it is a coarse-grained sandstone and is looked upon by the railway engineers as incomparably superior to the stone found at Medaini-Salih or El Oula, further down the line.

Fig. 4.



The village of Tebuk.

There is an abundant water-supply at Tebuk. It comes from two main sources—a spring in the middle of the village and wells. The spring bubbles up in the middle of a reservoir (or *burket*), of which there are three here, situated, as usual, immediately under the protecting walls of the *kala'at.* The water flows to the other reservoirs and thence by primitive irrigation channels to all parts of the village and appears to be ultimately lost in the sand again. In the main reservoir the water was breast deep; it was full of growing weeds and at the edges there was rather an offensive scum, but in the middle there was a bare patch of white sand and here the water could be seen foaming and bubbling up through the sand. The "head" must be considerable to produce such an effect, and it is not altogether easy to say where it comes from; but presumably it is from the distant hills to be seen on either side of the line. These

[1] No. I. was published in The Lancet of Sept. 26th, p. 971.

she is paid by the family employing her, save where a well-wisher bears the expense for a woman unable to do so herself. In all cases of lying-in or of prolonged illness on the mother's part a member of the committee visits to make sure that the work is being properly done. This system is stated to have been very successful in Frankfort and, so far as lying-in mothers are concerned, has been adopted by the Jewish community of the East-end of London. The lying-in woman of the working class in England, even when she is able to pay for what she needs, is often in a precarious position. It is not easy to procure female help of any kind and, of course, it is far more difficult to obtain the assistance of a woman possessing skill and experience. It is well known that the Midwives Act does not meet the situation.

THE AGE OF PARENTS A FACTOR IN THE ETIOLOGY OF RICKETS.

Dr. P. Gelati recently studied the records of the out-patient clinic for children in connexion with the Parma medical school and found (says *La Semaine Médicale* of Sept. 23rd, quoting from the June number of *Pediatria*) that out of 3121 little patients who were taken for advice during a period of about four years 615 were rachitic, that is 19·71 per cent. Contrary to expectation he found that those coming from country districts were more frequently affected than those who lived in towns, the percentage of rachitics being 17·26 for the town-bred children and 24·77 for those from rural districts. Regarding the influence of the parents' age, the statistics showed unmistakably that the older they were at the time of the children's birth the more likely the children were to show signs of rickets. Thus in the case of parents below 20 years of age the percentage of rickety children was only 11·6; in that of parents between 20 and 30 years of age, 19·2; and in that of those over 30 years of age as much as 22·2. Though the age of the parents has such a marked influence on the frequency of rickets this factor is of far less importance than that of breast-feeding and this was fully proved by Dr. Gelati's researches. It is worthy of remark that he found that rural parents were less prolific than those living in towns.

READING IN BED.

READING in bed at night is, speaking generally at all events, an unhealthy practice as we have previously had occasion to remark[1] and there is fortunately a tolerably universal consensus of opinion amongst the public that the habit is better avoided. Probably the fear of its being the cause of a conflagration of the bed curtains and perhaps of the whole house has had something to do with the feeling against it in the past, and the danger no doubt was an obvious objection in the days when flimsy bed curtains were fashionable and when the electric light, which is practically free from such danger and which does not vitiate the air as gas and oil lamps do, was not available. Dr. Hugo Feilchenfeld of Berlin has recently made a study (recorded in the *Medicinische Klinik*) of the subject with the object of finding out exactly what harm is likely to result from reading in bed and in what circumstances the practice is most injurious. He finds the chief danger is to the eyes, partly because the light used is frequently insufficient and so placed as to dazzle them, and partly because it is difficult to hold the book so that full benefit is obtained from the use of both eyes. This is more particularly the case when the reader is lying on one side. Again, there is generally a temptation to hold the book too close to the eyes and this of itself tends to induce myopia. Very particularly is this result to be feared in the case of young persons whose eyes are not fully developed. For this reason boys and girls under 18 should be strictly forbidden to read in bed. Of course, persons suffering from errors of refraction—myopia, hypermetropia, astigmatism, and so on—are liable to increase the trouble by indulging in the practice. Notwithstanding all the objections which can rightly be urged against reading in bed, there are many aged, anxious, worried, and bedridden people to whom it would seem cruel to deny what may perhaps be almost their only luxury for fear of inducing some slight error of refraction. In these cases care should be taken that the light should be sufficiently brilliant, the eyes being shaded from it, and that the patient should lie on his back with the head and shoulders raised. In this way the dangers may be minimised. Referring to reading in bed in the daytime in ordinary cases of illness, how often do we see a patient, the foot of whose bed is towards the window, struggling with a book or newspaper held between himself and the light so that his eyes receive the glare of full daylight while the only illumination of the printed page is that due to the diffused light in the room! A suggestion that during the daytime or part of the daytime the patient's head, together with the bolster and pillows, should be transferred to the foot of the bed is often gratefully received, as not only is reading rendered much more pleasant but the change of position and of aspect night and morning is almost always agreeable, relieving as it does to some extent the irksomeness of confinement to bed.

TUBERCULOUS SEPTICÆMIA.

AT a meeting of the Académie de Médecine of Paris on July 28th M. L. Landouzy and M. L. Laederich called attention to a form of tuberculosis—tuberculous septicæmia—which is not generally recognised. They related the following case. A thin, miserable-looking boy, aged 16 years, was admitted into hospital on July 17th, 1907. Three months previously he went to Paris to assume the occupation of groom and at once began to waste. He soon contracted measles which ran a benign course. Four weeks later he was feverish and suffered from pains in the joints which compelled him to keep to bed. The pains began in the left ankle-joint and then most of the large joints were attacked. On admission, on the fifteenth day, the temperature ranged irregularly from 100·4° to 103·1° F. The right knee was the only joint which remained affected; it was hot, swollen, and very painful on palpation and movement. But what attracted most attention was polymorphous erythema on the trunk and thighs. On the trunk it was papular and circinate; on the thighs nodular and indurated. Examination of the heart showed prolongation and muffling of the first sound at the apex and slight undulation of the chest wall. There was no cough, but careful examination of the thorax revealed induration and congestion at the left apex. In spite of the administration of large doses of salicylate the fever persisted. The knees and wrists became swollen and painful. The erythema disappeared after administration of potassium iodide. But a few days later it recurred and after some days regressed. The arthritis diminished but at the same time the cardiac affection increased. The first sound became blowing, the heart enlarged, and the undulation of the chest wall increased (signs of mitral insufficiency and adherent pericardium). During August several hard and tender nodules of the size of lentils appeared in the occipital region and seemed to be attached to the bone. After some days they disappeared to reappear a fortnight later. In the same time three or four similar nodules appeared on the elbows. A few days later all the nodules permanently disappeared. Simultaneously signs of pleurisy appeared, first on the right side, then on the left. Exploratory puncture yielded only a is more or less the centre. Their sheikhs, as also those of the other principal bedouin tribes, were concentrating at Tebuk in order to meet the railway authorities and come to an agreement for guaranteeing the security of the line from attack, and it was by a fortunate coincidence that the journey of the Commission took place just at this moment. On the return journey I had occasion to meet, at Ma'an and in the desert between Ma'an and Petra, five of the principal sheikhs of the Howeitat tribe, who inhabit the region between Ma'an and the Gulf of Akaba; and in Damascus one of the sheikhs of the Fakir tribe (the cousin of Mutlak, the chief) and Sheikh Hamud, the head of the Welad Ali tribe. The Fakir tribe live in the region to the east and north-east of Medaini-Salih; the Welad Ali in that lying between Medaini-Salih and Medina. Practically the only tribe to be considered in connexion with the safety of the future lazaret at Tebuk is that of the Beni Attiyeh, and the Commission made a provisional arrangement with Sheikh Harb under which, in return for a small payment, his tribe would guarantee the security of the lazaret and also furnish the required number of men to act as *gardes sanitaires*. The railway has its principal hospital for sick employees at Tebuk. It is a long, one-storeyed building of stone, with roof of Marseilles tiles. It contains one long ward 44·5 metres (say 140 feet) in length and 6 metres wide, and two small rooms at each end; the baths and service rooms are in separate outbuildings. A branch from the main line of the railway runs up to this hospital. At the time of our visit there were about 60 patients under treatment; they were mostly Italian labourers and Turkish troops who had been employed in laying down the line. The exterior and interior of this hospital are shown in the photographs reproduced here (Fig. 6 and Fig. 7).

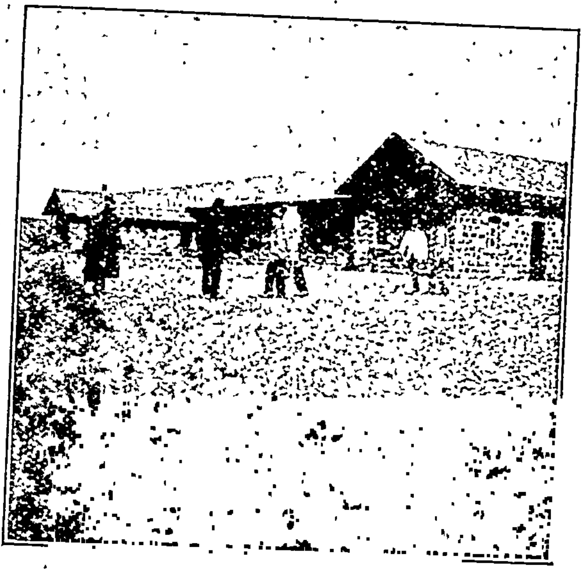
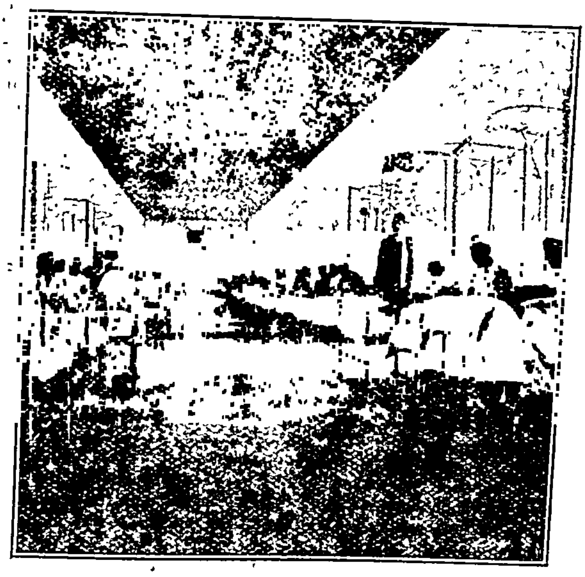
FIG. 6.



The Hedjaz Railway Hospital at Tebuk.

FIG. 7.



Interior of the Tebuk Hospital.

There are practically no meteorological observations available at Tebuk. I have, however, noted that on June 8th, 1908, the thermometer in the shade stood at 30° C. at 10 A.M., at 34° at 1 P.M., and at 36° at 2.30 P.M.; and that on the 10th it rose to 37° C. at 1 P.M. and to 39° at 2.30. Meissner Pasha tells me that the day temperatures at Tebuk are about the same as those at Medaini-Salih but that the nights are incomparably cooler. The nights, it may be added, were always cool during our brief journey on the line, the thermometer sinking to 25° C. (77° F.) and even lower. Sandstorms are commoner at Tebuk than at Ma'an, but much less frequent than at Medaini-Salih; they occur at Tebuk about once every two months.

(*To be continued.*)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE winter session commenced in Birmingham on the first Monday in October and in the Medical Faculty it was inaugurated in the usual way by a conversazione which was, if anything, more than usually successful. The Dean of the Medical Faculty, Professor H. G. Barling, aided by Professor R. Saundby and Mr. John Humphreys, received the numerous guests in the Founders' Room of the University Club, whence they wandered to the various laboratories, lecture rooms, and museums, where a series of attractive exhibitions were displayed. Professor Barling had provided a most excellent concert, and the audience was enthusiastic in its appreciation of Mrs. Ranalow's songs and Messrs. Heath's, Lloyd's and Pickup's instrumental music. Great interest was shown in the radiographs exhibited by Mr. J. Hall-Edwards and Dr. A. Emrys Jones and in the preparations of various types of tubercle and tubercle bacilli, and the photo-micrographs illustrating phases of the life-history of the malarial parasite, the fluid from a plague bubo, and the eggs of various parasites, which were exhibited in the Pathological Laboratory.

The Provident Dispensaries Scheme.

The scheme for the establishment in Birmingham of a series of provident dispensaries, to which I drew attention in my last letter, was carefully and fully expounded to a meeting of the Birmingham and District General Medical Practitioners' Union on Sept. 29th by Mr. Neville Chamberlain. The main objects of the scheme are to relieve the out-patient departments of the hospitals, to supplement the existing provident agencies, and to secure to the medical profession some remuneration from patients who are able to pay something for the work done for them. Mr. Chamberlain pointed out that he and those who had been working with him recognised that hospitals competed with each other for out-patients and in their reports pointed with pride to the number of cases treated. The General Hospital was certainly trying to break through the system which had been established and after giving first aid to certain cases it requested them not to attend again but to go elsewhere for further treatment. One hospital alone, however, could do little, for the people turned away from it could go to some similar institution. Therefore, coöperation between the hospitals was essential if success was to be obtained. To secure such coöperation it was necessary that the staffs of the hospitals should be convinced that the patients turned away could secure satisfactory treatment elsewhere, and the object of the new scheme was to provide the necessary she is paid by the family employing her, save where a well-wisher bears the expense for a woman unable to do so herself. In all cases of lying-in or of prolonged illness on the mother's part a member of the committee visits to make sure that the work is being properly done. This system is stated to have been very successful in Frankfort and, so far as lying-in mothers are concerned, has been adopted by the Jewish community of the East-end of London. The lying-in woman of the working class in England, even when she is able to pay for what she needs, is often in a precarious position. It is not easy to procure female help of any kind and, of course, it is far more difficult to obtain the assistance of a woman possessing skill and experience. It is well known that the Midwives Act does not meet the situation.

THE AGE OF PARENTS A FACTOR IN THE ETIOLOGY OF RICKETS.

Dr. P. Gelati recently studied the records of the out-patient clinic for children in connexion with the Parma medical school and found (says *La Semaine Médicale* of Sept. 23rd, quoting from the June number of *Pediatria*) that out of 3121 little patients who were taken for advice during a period of about four years 615 were rachitic, that is 19·71 per cent. Contrary to expectation he found that those coming from country districts were more frequently affected than those who lived in towns, the percentage of rachitics being 17·26 for the town-bred children and 24·77 for those from rural districts. Regarding the influence of the parents' age, the statistics showed unmistakably that the older they were at the time of the children's birth the more likely the children were to show signs of rickets. Thus in the case of parents below 20 years of age the percentage of rickety children was only 11·6; in that of parents between 20 and 30 years of age, 19·2; and in that of those over 30 years of age as much as 22·2. Though the age of the parents has such a marked influence on the frequency of rickets this factor is of far less importance than that of breast-feeding and this was fully proved by Dr. Gelati's researches. It is worthy of remark that he found that rural parents were less prolific than those living in towns.

READING IN BED.

READING in bed at night is, speaking generally at all events, an unhealthy practice as we have previously had occasion to remark[1] and there is fortunately a tolerably universal consensus of opinion amongst the public that the habit is better avoided. Probably the fear of its being the cause of a conflagration of the bed curtains and perhaps of the whole house has had something to do with the feeling against it in the past, and the danger no doubt was an obvious objection in the days when flimsy bed curtains were fashionable and when the electric light, which is practically free from such danger and which does not vitiate the air as gas and oil lamps do, was not available. Dr. Hugo Feilchenfeld of Berlin has recently made a study (recorded in the *Medicinische Klinik*) of the subject with the object of finding out exactly what harm is likely to result from reading in bed and in what circumstances the practice is most injurious. He finds the chief danger is to the eyes, partly because the light used is frequently insufficient and so placed as to dazzle them, and partly because it is difficult to hold the book so that full benefit is obtained from the use of both eyes. This is more particularly the case when the reader is lying on one side. Again, there is generally a temptation to hold the book too close to the eyes and this of itself tends to induce myopia. Very particularly is this result to be feared in the case of young persons whose eyes are not fully developed. For this reason boys and girls under 18 should be strictly forbidden to read in bed. Of course, persons suffering from errors of refraction—myopia, hypermetropia, astigmatism, and so on—are liable to increase the trouble by indulging in the practice. Notwithstanding all the objections which can rightly be urged against reading in bed, there are many aged, anxious, worried, and bedridden people to whom it would seem cruel to deny what may perhaps be almost their only luxury for fear of inducing some slight error of refraction. In these cases care should be taken that the light should be sufficiently brilliant, the eyes being shaded from it, and that the patient should lie on his back with the head and shoulders raised. In this way the dangers may be minimised. Referring to reading in bed in the daytime in ordinary cases of illness, how often do we see a patient, the foot of whose bed is towards the window, struggling with a book or newspaper held between himself and the light so that his eyes receive the glare of full daylight while the only illumination of the printed page is that due to the diffused light in the room! A suggestion that during the daytime or part of the daytime the patient's head, together with the bolster and pillows, should be transferred to the foot of the bed is often gratefully received, as not only is reading rendered much more pleasant but the change of position and of aspect night and morning is almost always agreeable, relieving as it does to some extent the irksomeness of confinement to bed.

TUBERCULOUS SEPTICÆMIA.

AT a meeting of the Académie de Médecine of Paris on July 28th M. L. Landouzy and M. L. Laederich called attention to a form of tuberculosis—tuberculous septicæmia—which is not generally recognised. They related the following case. A thin, miserable-looking boy, aged 16 years, was admitted into hospital on July 17th, 1907. Three months previously he went to Paris to assume the occupation of groom and at once began to waste. He soon contracted measles which ran a benign course. Four weeks later he was feverish and suffered from pains in the joints which compelled him to keep to bed. The pains began in the left ankle-joint and then most of the large joints were attacked. On admission, on the fifteenth day, the temperature ranged irregularly from 100·4° to 103·1° F. The right knee was the only joint which remained affected; it was hot, swollen, and very painful on palpation and movement. But what attracted most attention was polymorphous erythema on the trunk and thighs. On the trunk it was papular and circinate; on the thighs nodular and indurated. Examination of the heart showed prolongation and muffling of the first sound at the apex and slight undulation of the chest wall. There was no cough, but careful examination of the thorax revealed induration and congestion at the left apex. In spite of the administration of large doses of salicylate the fever persisted. The knees and wrists became swollen and painful. The erythema disappeared after administration of potassium iodide. But a few days later it recurred and after some days regressed. The arthritis diminished but at the same time the cardiac affection increased. The first sound became blowing, the heart enlarged, and the undulation of the chest wall increased (signs of mitral insufficiency and adherent pericardium). During August several hard and tender nodules of the size of lentils appeared in the occipital region and seemed to be attached to the bone. After some days they disappeared to reappear a fortnight later. In the same time three or four similar nodules appeared on the elbows. A few days later all the nodules permanently disappeared. Simultaneously signs of pleurisy appeared, first on the right side, then on the left. Exploratory puncture yielded only a associated some permanent memorial of two of its most distinguished citizens. The movement was taken up with enthusiasm, and the painting of Sir Clifford Allbutt's portrait was entrusted to Mr. A. S. Cope, A.R.A., and that of Mr. Teale to Mr. W. W. Ouless, R.A. A pleasing ceremony was held at the General Infirmary on Oct. 2nd when, in the presence of a large meeting of the subscribers and happily also in the presence of the recipients of the honour, Dr. J. E. Eddison, speaking on behalf of the subscribers, presented the portraits to the chairman of the board of the infirmary, with a request that they should be hung on the walls of that institution. Though the subscribers to the fund included, not only many medical men, but a large number of the general public, no one could have been found more qualified by long personal friendship with his two colleagues and by the possession of tact and ability to say the right thing in the right way than Dr. Eddison. He reminded his audience that Dr. Allbutt and Mr. Teale were appointed to the infirmary in the same year—namely, in 1864—and that they resigned their positions on the active staff on the same day after 20 years' service. In the building of the infirmary, which was opened in 1869, they took an active part and much of the excellence of the arrangements therein was due to their care and supervision. Speaking with some natural restraint of eulogy in their presence he paid a graceful compliment to the excellence and high character of the professional and public work both of Sir Clifford Allbutt and Mr. Teale. Mr. Charles Lupton, the treasurer of the infirmary, having accepted the portraits on behalf of the institution, Sir Clifford Allbutt and Mr. Teale briefly addressed the meeting. The two portraits are unquestionably excellent and are worthy as works of art to a place of honour on the walls of the infirmary.

---

[1] See THE LANCET, Dec. 8th, 1900, p. 1145.

Opening of the Medical Session.

After the presentation of the portraits at the infirmary the winter session of the Faculty of Medicine was informally opened by the distribution of the prizes gained by the students during the past year. The chair was taken by Mr. Teale and there were present Dr. N. Bodington, the Vice-Chancellor of the University; the Right Hon. C. G. Milnes Gaskell; many members of the teaching staff; Professor A. S. F. Grünbaum, the Dean of the Faculty of Medicine; and Sir Clifford Allbutt who distributed the prizes and awards. A short address was then delivered by Sir Clifford Allbutt, which was listened to by the students with marked appreciation. I have heard Sir Clifford Allbutt speak on many and varied occasions during the last 25 years, sometimes on occasions more or less formal, sometimes on discussions at the medical societies and elsewhere, yet I doubt if I have ever heard him use his natural gifts and his absolute mastery of the English language with more grace and wisdom. His peroration was one that will long remain in the minds of all who heard it.

(FROM OUR OWN CORRESPONDENTS.)

The Winter Session in Edinburgh: Introduction of Professor Walker and Professor Caird.

THE winter session of the medical classes in Edinburgh was opened on Oct. 1st, about a fortnight earlier than has hitherto been usual. Although the date was in the middle of the week the students turned up in commendable numbers. The new professor of chemistry delivered his introductory address at 10 o'clock in the McEwan Hall to a large audience. Principal Sir William Turner occupied the chair and in a few suitable words introduced Professor James Walker. The lecturer took for his theme the question of the "Transmutation of Metals," a subject which he treated in a very interesting manner. In concluding his lecture he struck a note which it may be hoped may often be struck again. He said that he was not a believer in science in the sense that any ultimate value to mankind by the discoveries of science should be rigorously excluded from the mind of the scientist. No better stimulus could be given to the scientist than to know that his work if successful might be of use in the daily life of his fellow men. A pure scientist was a pure myth. Those of them who did not go out into the world and did not quite sever the leading strings of their *alma mater* were in great danger of mistaking the university for the universe. The greater men of science whose thought actuated and stimulated their own and succeeding generations fell into no such error. They thought of their work not only in relation to the progress of science but also to the betterment of mankind. At noon, in the same hall, the Principal again presiding, Professor F. M. Caird was introduced to a large audience. Professor Caird gave a rapid but artistic survey of the development of surgery in Edinburgh from the year 1505. He showed the place which the first Munro occupied and the great influence exercised by John Bell. He compared hospital treatment then with now, adorning his lecture by excerpts from old case-books.

Resignation of Dr. J. Murdoch Brown.

Many old students of the Edinburgh school will regret to learn that Dr. Murdoch Brown has resigned his post as senior assistant physician to the Royal Infirmary on account of the continued unsatisfactory character of his health. This makes a vacancy at the infirmary, and it is satisfactory to know that there will be several eligible candidates.

The Medical Education of Women in Edinburgh.

Notwithstanding the agitation of the past summer the School of Medicine for Women, which has its headquarters at Surgeons' Hall, has had a gratifying opening of its winter session. Students have more than enough to occupy their minds with their undergraduate studies, for the present curriculum requires earnest thought and steadfast purpose if satisfactory results are to be attained.

The Future of the Glasgow Hospital for Skin Diseases.

The directors of the Glasgow Hospital for Skin Diseases have summoned a meeting of subscribers to consider the present position of the hospital. The history of the hospital is shortly as follows: It was founded in 1871 and in 1878 removed to its present building in Elmbank-street, where the treatment of outdoor patients was carried on. Accommodation for indoor treatment has been provided in the Western Infirmary of Glasgow under an agreement whereby, in return for a sum of £2000 contributed by the hospital towards the infirmary buildings, the hospital has enjoyed the use of two wards of ten beds each, male and female, in the infirmary, with the right of appointing the physician to those wards. Till his death that appointment was held by Sir Thomas McCall Anderson. Up to the end of last year 3208 patients obtained the benefit of treatment in those special wards. In view of the advantages which have resulted from this virtual union of the two institutions as regards the indoor department the directors think that the time has now come when it would be for the public advantage if the dispensary work now carried on at Elmbank-street were also transferred to the Western Infirmary buildings. There is already there a large and well-equipped general dispensary, and the managers of the Western Infirmary are not only prepared but desire to open a dispensary for skin diseases as a part thereof. That this would also be of advantage to the students there is no doubt. If this scheme is carried out the Glasgow Hospital for Skin Diseases will cease to exist as a separate institution. It is to be laid before the subscribers that a lectureship on dermatology should be founded in the University of Glasgow with £2500 of the hospital's funds, the free balance of the assets of the hospital thereafter to be handed over to the Western Infirmary for the endowment of beds in the wards appropriated to the treatment of skin disease. It is also suggested that the names of Sir Thomas McCall Anderson and Dr. A. B. Buchanan, the joint founders of the hospital, should be suitably associated with the scheme and that a record of the endowment of the beds should be placed on a tablet in the Western Infirmary. It is probable that this scheme will be endorsed by a meeting of subscribers shortly to be held. In that case the directors of the hospital will take steps to carry it into effect by means of a Provisional Order under the Private Legislation Procedure (Scotland) Act, 1899, to be promoted by them.

Extension of Aberdeen City Hospital.

A special meeting of the public health committee of the Aberdeen town council was held on Oct. 1st in order to consider the adoption of the plans of the city architect for the extension of the City Hospital. The committee approved of the plans with the exception of the proposed additional new pavilion for phthisical patients, the committee having not nearly forty years, was broken in several parts of England, Wales, and Scotland. As has been already remarked, the heat was accompanied by extreme humidity. During an average fine, hot day in summer the *relative humidity (the* percentage of the possible amount of water vapour in the air) ranges from about 75 per cent. in the early morning to between 40 and 55 by the afternoon, increasing again to about 75 per cent. after sunset. Last week, however, the figures were not far below 100 per cent., except occasionally for a short time during the afternoon, and then not often below 70 per cent. In very dry countries the amount of humidity with such temperatures as are now under consideration ranges from about 20 to 40 per cent. The conditions that brought such great heat about were fairly simple and would have produced warm weather even in midwinter. The United Kingdom was situated between a large high-pressure system or anticyclone, which lay over the central countries of Europe and the Baltic region and extended across the North Sea, and a very extensive low-pressure area which occupied the space on the Atlantic between the Azores and Iceland. Such a distribution of pressure compelled the air from the southern regions of the Atlantic to flow in a steady stream over this country and as it encountered a cloudless sky when passing over the land its already high temperature became greatly accentuated. During the latter part of the period the stream of warm air from the south ceased in the south and east of England, but as it was succeeded by a gentle flow of warm air from the continent the temperature underwent very little modification.

THE EARLY DIAGNOSIS OF ENTERIC FEVER BY BLOOD CULTURE.

IN 1906 Conradi showed that in enteric fever the bacillus could be cultivated from the blood in much larger percentages of cases by using ox bile as a medium than by using the ordinary media. This has been confirmed by several writers. In the *Boston Medical and Surgical Journal* of June 4th Dr. O. R. Mabee and Dr. A. E. Taft have reported a series of 120 consecutive cases in which the patients were admitted to the Boston City Hospital as suffering from enteric fever during an epidemic in that city and cultures were made from the blood. Fresh ox bile was used as a medium in 90 cases and inspissated bile in the other 30, with equally good results. Five cubic centimetres of the fresh bile were placed in tubes and sterilised in an autoclave for 30 minutes at 15 pounds pressure. The blood was obtained from the lobe of the ear. The skin was cleansed with soap and water and then with 70 per cent. of alcohol. This was allowed to evaporate and then a deep puncture was made with the point of a small scalpel. The blood was collected in sterile pipettes. It was at once transferred to the ox bile before clotting could take place. After incubation at 37° C. for six hours platinum loops of the culture were transferred to plain bouillon (as the dark colour of the bile rendered detection of a few microbes difficult). In most of the cases in which the bacillus was present it was found in the first transfer to the bouillon; if not, other transfers were made from the bile culture after longer periods of incubation. If the fourth transfer showed no bacilli the case was regarded as negative. Of the 120 patients 98 developed typical symptoms of enteric fever. The percentage of positive results in the first week was 95, in the second 17·7, and in the third 14·2. Comparing these results with the Widal reaction in the same cases the percentage of positive results in the first week was five, and in the second and third weeks 100. The percentage of positive results from cultures in the first week corresponds with that of other observers, but in the second and third week is much lower than that of some observers who took a much larger quantity of blood (at least two and a half cubic centimetres) from a vein in the arm. This suggests that the number of bacilli in the blood in the second and third weeks is much lower than in the *first*. In the 22 cases admitted under the diagnosis of enteric fever, which proved to be incorrect, blood cultures were negative except in one, in which the staphylococcus pyogenes aureus was found. The value of blood culture in diagnosis in the first week of enteric fever, when the Widal reaction is generally absent, is therefore great. A cubic centimetre of blood is then sufficient for each culture, but in the second and third week a larger quantity gives a higher percentage of positive results.

A SCIENTIFIC PRIEST ON THE DANGERS OF HOLY WATER.

THE sanitary dangers lurking in "holy water" have often been referred to by medical men. They have recently been scientifically studied by a monk, Fr. Augustin Gemelli, who is himself a highly qualified medical man. He publishes his results in the *Scuola Cattolica*. Each cubic centimetre of holy water in the basins in the church of Santa Croce, Turin, taken from the surface contained 150,000 microbes, while a cubic centimetre taken from the bottom contained no less than 6,000,000 microbes. He injected this water into animals and found that it always killed them, the causes of death being tuberculosis, colitis, or diphtheria. He does not think a daily cleansing with corrosive sublimate sufficient, but recommends a new form of holy water receptacle so constructed that persons instead of dipping their fingers into it can obtain three drops of water by pressing a button. A vessel of this nature has been placed in the church of Vergiate, Milan.[1] Fr. Gemelli turned his attention also to the grilles in the confessional boxes. Water which had been used for washing these only contained 25 microbes per cubic centimetre and when injected into animals only proved fatal to 10 per cent. of them.

RESULTS OF X RAY TREATMENT OF RINGWORM.

THE recently issued report of the Metropolitan Asylums Board for 1907 contains some interesting statistics bearing on the results of the x ray method of treatment of cases of ringworm in the Downs Ringworm School provided by that Board. It is stated that the duration of residence of these cases in the above-mentioned school before this new method of treatment was introduced averaged about 18 months, whereas the average period of detention of 100 cases so treated in 1906 did not exceed 5·73 months, or, if calculated from the time this treatment actually began, was only 4·49 months. During 1907 the average period of detention of the last 100 cases treated by x rays and discharged prior to Dec. 31st last was 6·21 months. The report states that owing to the demand made in this ringworm school on the apparatus, which has since been enlarged, many cases had to wait some time before being so treated, and if the period of detention in these 100 cases is calculated from the date of the commencement of the treatment it averaged only 5·33 months. It is pointed out that the slight increase of average detention of cases in 1907, compared with that in 1906, was largely due to delay in discharging cases last year caused by small outbreaks of whooping-cough and chicken-pox in these schools. It is satisfactory to note that the number of cases under treatment in the Downs school, which averaged 554 during the three years 1903–04–05, had declined to 339 on Dec. 31st, 1906, and on Dec. 31st last had further fallen to 329. This decrease was in great measure due to the associated some permanent memorial of two of its most distinguished citizens. The movement was taken up with enthusiasm, and the painting of Sir Clifford Allbutt's portrait was entrusted to Mr. A. S. Cope, A.R.A., and that of Mr. Teale to Mr. W. W. Ouless, R.A. A pleasing ceremony was held at the General Infirmary on Oct. 2nd when, in the presence of a large meeting of the subscribers and happily also in the presence of the recipients of the honour, Dr. J. E. Eddison, speaking on behalf of the subscribers, presented the portraits to the chairman of the board of the infirmary, with a request that they should be hung on the walls of that institution. Though the subscribers to the fund included, not only many medical men, but a large number of the general public, no one could have been found more qualified by long personal friendship with his two colleagues and by the possession of tact and ability to say the right thing in the right way than Dr. Eddison. He reminded his audience that Dr. Allbutt and Mr. Teale were appointed to the infirmary in the same year—namely, in 1864—and that they resigned their positions on the active staff on the same day after 20 years' service. In the building of the infirmary, which was opened in 1869, they took an active part and much of the excellence of the arrangements therein was due to their care and supervision. Speaking with some natural restraint of eulogy in their presence he paid a graceful compliment to the excellence and high character of the professional and public work both of Sir Clifford Allbutt and Mr. Teale. Mr. Charles Lupton, the treasurer of the infirmary, having accepted the portraits on behalf of the institution, Sir Clifford Allbutt and Mr. Teale briefly addressed the meeting. The two portraits are unquestionably excellent and are worthy as works of art to a place of honour on the walls of the infirmary.

In concluding his lecture he struck a note which it may be hoped may often be struck again. He said that he was not a believer in science in the sense that any ultimate value to mankind by the discoveries of science should be rigorously excluded from the mind of the scientist. No better stimulus could be given to the scientist than to know that his work if successful might be of use in the daily life of his fellow men. A pure scientist was a pure myth. Those of them who did not go out into the world and did not quite sever the leading strings of their *alma mater* were in great danger of mistaking the university for the universe. The greater men of science whose thought actuated and stimulated their own and succeeding generations fell into no such error. They thought of their work not only in relation to the progress of science but also to the betterment of mankind. At noon, in the same hall, the Principal again presiding, Professor F. M. Caird was introduced to a large audience. Professor Caird gave a rapid but artistic survey of the development of surgery in Edinburgh from the year 1505. He showed the place which the first Munro occupied and the great influence exercised by John Bell. He compared hospital treatment then with now, adorning his lecture by excerpts from old case-books.

Resignation of Dr. J. Murdoch Brown.

Many old students of the Edinburgh school will regret to learn that Dr. Murdoch Brown has resigned his post as senior assistant physician to the Royal Infirmary on account of the continued unsatisfactory character of his health. This makes a vacancy at the infirmary, and it is satisfactory to know that there will be several eligible candidates.

The Medical Education of Women in Edinburgh.

Notwithstanding the agitation of the past summer the School of Medicine for Women, which has its headquarters at Surgeons' Hall, has had a gratifying opening of its winter session. Students have more than enough to occupy their minds with their undergraduate studies, for the present curriculum requires earnest thought and steadfast purpose if satisfactory results are to be attained.

The Future of the Glasgow Hospital for Skin Diseases.

The directors of the Glasgow Hospital for Skin Diseases have summoned a meeting of subscribers to consider the present position of the hospital. The history of the hospital is shortly as follows: It was founded in 1871 and in 1878 removed to its present building in Elmbank-street, where the treatment of outdoor patients was carried on. Accommodation for indoor treatment has been provided in the Western Infirmary of Glasgow under an agreement whereby, in return for a sum of £2000 contributed by the hospital towards the infirmary buildings, the hospital has enjoyed the use of two wards of ten beds each, male and female, in the infirmary, with the right of appointing the physician to those wards. Till his death that appointment was held by Sir Thomas McCall Anderson. Up to the end of last year 3208 patients obtained the benefit of treatment in those special wards. In view of the advantages which have resulted from this virtual union of the two institutions as regards the indoor department the directors think that the time has now come when it would be for the public advantage if the dispensary work now carried on at Elmbank-street were also transferred to the Western Infirmary buildings. There is already there a large and well-equipped general dispensary, and the managers of the Western Infirmary are not only prepared but desire to open a dispensary for skin diseases as a part thereof. That this would also be of advantage to the students there is no doubt. If this scheme is carried out the Glasgow Hospital for Skin Diseases will cease to exist as a separate institution. It is to be laid before the subscribers that a lectureship on dermatology should be founded in the University of Glasgow with £2500 of the hospital's funds, the free balance of the assets of the hospital thereafter to be handed over to the Western Infirmary for the endowment of beds in the wards appropriated to the treatment of skin disease. It is also suggested that the names of Sir Thomas McCall Anderson and Dr. A. B. Buchanan, the joint founders of the hospital, should be suitably associated with the scheme and that a record of the endowment of the beds should be placed on a tablet in the Western Infirmary. It is probable that this scheme will be endorsed by a meeting of subscribers shortly to be held. In that case the directors of the hospital will take steps to carry it into effect by means of a Provisional Order under the Private Legislation Procedure (Scotland) Act, 1899, to be promoted by them.

Extension of Aberdeen City Hospital.

A special meeting of the public health committee of the Aberdeen town council was held on Oct. 1st in order to consider the adoption of the plans of the city architect for the extension of the City Hospital. The committee approved of the plans with the exception of the proposed additional new pavilion for phthisical patients; the committee having not themselves for examination with a view to diagnosis and treatment. In placing patients under hospital treatment the assistance of the police was required in the case of five men and six women. On 44 occasions the aid of the police was requisitioned when the sources of infection were to be sought. In accordance with the law that punishes with imprisonment for not more than three years those who, conscious of or suspicious of venereal disease in themselves, infect or expose to infection others by cohabitation or improper intercourse, eight men and 13 women were prosecuted; of these two men and six women were convicted and sentenced. In acknowledgment of the fact that children suffering from hereditary syphilis are themselves a great source of infection, efforts have been made of late years to educate mothers and foster-mothers as to the true nature of the disease, and to prevent as far as possible such children being adopted by families with healthy offspring. This movement has been largely helped by a recent law which enacts that "he who conscious of or suspicious of infectious syphilitic disease in a child, employs a nurse for such a child, or puts it out to nurse, is liable to fine or imprisonment not exceeding six months." Owing to the difficulty experienced in finding suitable homes, these children have often to spend years in hospital, whereas in Sweden Professor Welander's nursing home provides for just such cases.

ENGLISH URBAN MORTALITY DURING THE PAST SUMMER.

THE annual rate of mortality during the three months ending with September in London and in the 75 other largest English towns dealt with in the Registrar-General's weekly returns, having an aggregate population of more than 16,000,000, did not exceed 13·4 per 1000, notwithstanding a marked increase during August. This rate exceeded the unprecedentedly low rate in the corresponding period of last year by 1·2 per 1000, but was 1·9 below the mean rate in the same towns in the third quarters of the four years 1904–07. The deaths registered in these 76 towns during last quarter exceeded the low number returned in the corresponding quarter of 1907 by 5311, of which excess 4601 were due to increase in the number of deaths resulting from diarrhœa. The exceptionally low death-rate during the summer quarter of 1907, more especially the low rate due to diarrhœa, was the result of the remarkably low temperature that prevailed during those three months. In the third quarter of last year only 510 deaths were referred to diarrhœa in London, equal to an annual rate of but 0·46 per 1000, whereas during the same period of this year the number rose to 1645, equal to a rate of 1·37 per 1000; in the corresponding quarters of the ten years 1897–1906, however, the mean annual rate from this disease was equal to 2·72 per 1000. The rate of mortality in the summer quarter is undoubtedly governed mainly by meteorological conditions, through the varying fatality of diarrhœa, almost entirely infantile. Infant mortality in the 76 large English towns during last quarter was equal to 146 per 1000 registered births, exceeding by 37 per 1000 the mean rate during the cool summer quarter of last year; it was, however, very considerably below the rate that prevailed in these towns in the corresponding quarters of 1905 and 1906, when it was 186 and 209 per 1000 respectively. In London the rate of infant mortality last quarter did not exceed 132 per 1000, while the mean rate during the quarter in the 75 provincial towns was equal to 151 per 1000. Infant mortality last quarter in London was 14·3 per cent. below the mean rate in the three preceding corresponding quarters, whereas in the 75 provincial towns the rate was not more than 12·7 per cent. below the same average. These figures imply more progress in checking the waste of infant life due to ignorant and neglectful treatment in London than in the aggregate of the 75 provincial towns. Due allowance being made for the meteorological conditions of the past summer, the mortality statistics relating to the largest English towns afford evidence, however, of generally improving sanitary conditions, both as regards infant mortality and the preventable fatality of summer diarrhœa.

VARICOSE EPIGASTRIC VEINS FOLLOWING PHLEBITIS.

IN the *Yale Medical Journal* for July Dr. J. E. Lane has reported a case in which phlebitis had an unusual sequel—varicose epigastric veins. An Italian shophand, aged 17 years, complained of a sore on the left leg and severe pain in both legs when standing or walking. Seven or eight years before he suffered from enteric fever and was confined to bed for six months. During most of the time both legs were swollen and painful. For about a month there was auditory and motor aphasia which disappeared gradually. In the past two years there had been at different times sores on the legs which healed under treatment. Examination showed on the front and outer surface of the right leg just above the ankle the scars of two varicose ulcers. On the inner surface of the left leg just above the ankle was a clean ulcer about an inch in diameter. The legs were œdematous up to the knees and the superficial veins of this region were much enlarged. On the left side of the trunk two dilated veins stood out prominently. One, the superficial thoracico-epigastric, started in the groin and ran up the trunk to the axilla connecting the femoral vein with the axillary. The other ran nearer the middle line from the groin to the lower end of the sternum. It began as the superficial epigastric and above the umbilicus anastomosed with the superficial median xiphoid vein which empties into the transverse anastomotic or pre-xiphoid. This last vein connects the two internal mammary veins. The two dilated veins on the trunk were tortuous, especially in their lowest part, and the current of blood in them was from below up. Palpation revealed nothing abnormal in the saphenous or femoral vein. Evidently the attack of enteric fever was complicated with extensive phlebitis, involving the veins of both legs. The thrombosis must have left an obstruction, partial or complete, in the femoral or external iliac vein, compelling the blood to take the circuitous route described. The history of the aphasia is of interest on account of the rarity of cerebral embolism or thrombosis in enteric fever.

THE Hunterian Society's first lecture of the new session will be delivered at the London Institution, Finsbury-circus, on Wednesday, Oct. 14th, at 8.30 P.M., by Dr. James Mackenzie on the Bearing of Hunter's Work on Recent Advances in the Study of Heart Affections. All members of the medical profession are invited.

His Majesty the King has been pleased to grant permission to Dr. T. Vincent Dickinson to accept and to wear the order of Chevalier of the Crown of Italy, conferred on him by the King of Italy in recognition of his services as physician to the Italian Hospital.

ROYAL SOCIETY OF MEDICINE.—The Odontological Section of the Royal Society of Medicine is prepared to receive applications for grants in aid of the furtherance of scientific research in connexion with dentistry. Particulars and forms of application will be supplied by the Honorary Secretary, Scientific Research Committee, Odontological Section, Royal Society of Medicine, 20, Hanover-square, W.

adjacent to Belfast. For many years Mr. Wilson was a member of the Belfast board of guardians and he represented Whitehouse electoral division on the Belfast rural district council. A Licentiate of the Royal College of Physicians of Edinburgh (1865) and a Member of the Royal College of Surgeons of England (1865), Mr. Wilson practised at Whiteabbey, where he enjoyed the respect and confidence of a very large *clientèle* in the surrounding district.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Hygiene and Deep-Sea Fishermen.

WITH a view of improving the environment of deep-sea fishers both from a moral and hygienic point of view, the French Society of Hygiene has decided, on the initiative of its honorary president, to open a competition for the year 1909. The competition will be founded upon the results of an inquiry which is to be made into the dwelling places of deep-sea fishermen in a particular district. Candidates for the competition may choose their own district. Various prizes, including a gold medal, will be given. The competition will consist of two parts. The one will deal with statistics of the birth-rate, and with the death-rate and the disease incidence of preventable diseases. The other part of it will deal with the best description of the dwellings of the fishermen and with the expenses which would be incurred for really healthy dwellings, a proper water-supply, and adequate drainage, due notice, of course, being taken of existing conditions. Candidates will also be required to deal with the best way of ameliorating unhealthy conditions and of building new quarters for fishermen in the outskirts of maritime towns, especially in those which are fortified and therefore somewhat overcrowded.

The International Congress on Low Temperatures.

This congress was opened on Oct. 5th in the large theatre of the Sorbonne by M. Ruan, Minister of Agriculture, who delivered an address which was loudly acclaimed. The congress will last for a week.

(FROM OUR OWN CORRESPONDENT.)

The Practical Value of the Opsonic Index.

Dr. Turban of Davos and Dr. Baer of Reiboldsgrün writing in a recent number of the *Münchener Medicinische Wochenschrift* gave a report on their experiences concerning the opsonic index of tuberculous patients. Since November, 1906, the opsonic index has been determined in 84 tuberculous and in six non-tuberculous patients, more than 1000 examinations being made. It was remarkable that the results were nearly constant during a long time, a fact which, according to the authors, is a proof of the accuracy of the method. In healthy people the index proved to be very near to 1·0, the limits being between 0·9 and 1·1. Of the tuberculous patients in general 16·6 had a normal index—viz., 31 per cent. of the patients in the first stage, 22 per cent. of the patients in the second stage, and 9 per cent. of the patients in the third stage. Of patients with fever 0 per cent. and without fever 30 per cent. had a normal index. The following deviations of the index were observed: 1. The index was constantly above or below the normal; this was especially the case in patients with or without fever showing symptoms of an "active" tuberculous process. An "active" process means not only progressive disease but also cases where clinical observation makes it likely that toxins from the tuberculous focus have been absorbed into the circulation. 2. The index showed wide variations; this was observed in feverish patients with rapidly progressing tuberculosis of the lungs, and in every case of tuberculosis of the bones, joints, and kidneys. 3. The index being in the beginning low rose later to the normal or nearly to the normal. In these cases an amelioration of the local process, an improvement of the general state, and an increase of weight were observed together with the rise of the index. 4. The index having been constant became suddenly very low. This happened when a recent process in the lungs such as pleurisy occurred and also in cases with very acute destruction of the lungs. Not every feverish case showed a deviation; there were cases with high fever and acute destruction where the index was constantly during a fortnight from 0·65 to 0·67. In these cases a mixed infection with staphylococci must be assumed to be present. A low index, 0·62 to 0·71, was observed in a case of syphilis of the lungs; in this case the opsonins proved to disappear by boiling at 60°, whilst in tuberculosis they only diminish by 50 to 75 per cent. From the above observations the importance of the opsonic index for diagnosis and prognosis becomes obvious. A normal index does not exclude the presence of tuberculosis, but that of a progressive process; a low or high index proves the presence of active tuberculosis; wide deviation proves the presence of a progressive process; a constant low index shows that the process has become stationary; a gradual rise of a low or varying index occurs together with an improvement; and a rapid fall with a deterioration. The observers pointed out that a repeated determination of the index within a long space of time is essential and that this fact is prejudicial to the use of the index in practice. The determination of the index is, however, valuable in initial cases, where an abnormal index would prove the presence of an active process and the necessity of treatment. Concerning the influence of tuberculin treatment, first a negative and then a positive phase of the index of 0·2-3·0 was observed. Even after the administration of only one-millionth of T.O.A. a marked negative and positive phase was obtained, and during the treatment wide variations occurred. The authors are of opinion that during the tuberculin treatment observation of the temperature and of the local reaction is more important than the determination of the opsonic index.

Measures against Cholera.

The prevalence of cholera in St. Petersburg has naturally been a subject of careful attention for the Prussian and German Governments. The big traffic between Russia and the neighbouring parts of this country makes it very likely that at least some cases of cholera will be conveyed here. Indeed, some days ago a case was reported of a Russian lady who had come with her husband to Berlin and showed symptoms of cholera. She was immediately conveyed to the cholera pavilion of the Virchow Hospital, whilst the husband and the servants were placed under observation in a pavilion for suspected cases. The case caused some nervousness in Berlin, but on microscopical examination it proved to be not cholera but enteric fever. Meanwhile a conference has taken place of the delegates of the different German and Prussian administrative departments, of the medical, railway, seaport, police, and other authorities. It was decided to abstain at first from quarantine measures but to examine the passengers of the Russian immigrant trains who in great number pass through Germany for Hamburg and Bremen and also passengers of vessels coming from Russia. Arrangements will be made for the conveyance of eventual cases of cholera and to keep special pavilions ready in the hospitals of the greater towns. The water of the rivers coming from Russia will be daily examined by bacteriologists on the frontier as to the presence of cholera bacilli.

Poisoning by Raw Meat.

In the Virchow Hospital of Berlin recently 80 of the nurses suddenly became very ill with symptoms of poisoning. It was stated that the poisoning was due to spoiled meat which had been given to the nurses in a raw state for supper. Bacteriological examination showed the presence of paratyphoid bacilli. Fortunately no death occurred. Most of the nurses were able to return to work after one or two days and only a few had to be kept in bed for a week and to obtain leave because of great debility. The absence of so many nurses has of course caused some trouble in the nursing of the patients and nurses of other municipal hospitals and private nurses had to be fetched in haste to fill the vacant places to allow the service to continue. The event was discussed in the town council and the kitchen department of the hospital was severely criticised. The mayor stated that after an investigation of the matter it had been decided that raw meat would no longer be given either to the nurses or to the patients

Oct. 6th.

University College Hospital.—The annual dinner of the old and present students of this school was held in the library of the Medical School on Oct. 2nd, under the chairmanship of Professor A. H. Carter. The company numbered 122. There were only two toasts after that of "The King." The chairman proposed "University College Hospital Medical School," to which the Dean, Dr. H. Batty Shaw, replied. In his speech Professor Carter traced the history of the school and compared the old buildings with the commodious new medical school; he also spoke in terms of veneration of Sir William Jenner and others of his old teachers. The remaining toast was "The Chairman," which was given by Dr. H. Radcliffe Crocker.

Westminster Hospital.—The winter session was inaugurated by a dinner of past and present students held at the Wharncliffe Rooms, Hotel Great Central, on Oct. 2nd. The chair was taken by Dr. N. W. Bourns, senior anæsthetist to the hospital, who presided over a full attendance. When the loyal toasts had been honoured the chairman proposed "The Westminster Hospital and Medical School." He referred to the honour done to the school as well as to the recipient in the knighthood conferred by the King upon Dr. W. Allchin, a fitting recognition of his services to medicine, to medical education, and to the institution of which he had been so brilliant and tireless a servant. He then alluded to the grievous loss sustained by school and hospital alike by the deaths of Mr. E. P. Paton and Dr. Bertram L. Abrahams, who held the offices of dean and sub-dean respectively. Cut off in the prime of life, in the early flush of successful practice, they left a blank in the ranks, and he might say in the hearts of their colleagues that not even time could fill. Dr. F. de Havilland Hall, who responded, spoke of the benefits accruing from the centralisation of preliminary science teaching. Originally advocated by Sir William Allchin 20 years ago, it had become an accomplished fact so far as Westminster was concerned and the arrangement with King's College was working well. The toast of "The Students, Past and Present," was proposed by Mr. A. H. Tubby who dilated upon the happy relations always existing at Westminster between the staff and the students. Mr. G. L. Parsons, replying for the "Past," spoke at some length on the general practitioner's reflections upon medical education, of the uselessness of set lectures, and the immense value of bedside instruction and demonstration. Some teachers overlooked the fact that tables of data were best acquired from text-books, whilst clinical experience could only be handed on over the beds of actual patients. Mr. G. R. Ward, for the "Present," made a happy little speech appreciating the efforts of the staff to impart not only the facts but also the ethics and spirit of medicine, and the sympathy which they showed for other interests of the students. Mr. Charles Ryall proposed the health of the chairman, and Sir William Allchin that of the secretary, Mr. Carling.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Manchester.—In dealing with Manchester we are concerned with a population little short of 650,000 living in the midst of other aggregations of population which together with that of Manchester mount up to a very large figure. It does not in all approximate to that of the metropolis, but one day, when the rural lacunæ become filled up, it may do so, and perhaps our children's children may see a Manchester which has on numerous occasions extended its municipal limits, and towns which are now separate have become boroughs of the county of Manchester. There is not so much imagination in this picture as some people may think. Dr. James Niven, who deals with the local statistics in considerable detail, expresses the opinion when discussing the decreasing birth-rate that such diminution is due not merely to the prevention of conception but also in no small measure to the destruction of its fruits. He thinks, too, that the offspring must sometimes be injured by efforts to induce premature labour. Although the death-rate of Manchester is steadily declining, the relative position of the city in the firmament of the 76 great towns remains unaltered; it is still eighth from the bottom. Dr. Niven furnishes a table showing that although there was less pauperism in 1907 than in the previous three years the proportion of deaths occurring in public institutions to total deaths did not diminish. They were 26·5 of the total deaths, the highest proportion yet attained, and Dr. Niven thinks that this increasing tendency for the sick to obtain admission must have a material effect upon the death-rate, presumably diminishing it through careful nursing and the like. The death-rate for pulmonary tuberculosis in 1907, as compared with that in 1906, was stationary, but there was a pause in the ascent of the figures relating to malignant disease. The deaths from diarrhœa, which were 981 in 1906, fell to 291 in 1907, a fact for which the cool summer was no doubt largely responsible. With reference to the natural increase of the population of Manchester it is significant that the artisan and the Jewish populations of Manchester are increasing most rapidly. The increase is greatest in the Cheetham district, which means that the Jewish community is increasing at a greater rate than any other part of the population. Dr. Niven discusses certain aspects of scarlet fever in interesting fashion and he supplies figures showing that the disease is more infectious at its commencement than later, since the majority of cases occur within eight days after the first attack. The disease has, he concludes, a comparatively low degree of infectivity as compared with measles and whooping-cough, and, in his opinion, the modern view that the cutaneous eruption is toxic and non-specific is open to question; he thinks that it is safer to take early precautions to prevent the discharge of infection from the skin. In his view, we know nothing definite of the bacteriology of scarlet fever. Dr. Niven has been reflecting as to the causes which promote the annual rise of this disease. There is, he says, certainly a progressive though not a steady change of type going on. Part of this change of type may, he surmises, be due to notification, but he is more inclined to attribute it to the progressive diminution in filth near dwellings. In the matter of "return" cases of scarlet fever he expresses the opinion that there is no proof that prolonged detention in hospital diminishes the incidence of such cases. We cannot discuss the matter further here, but we may briefly quote Dr. Niven. It would, he thinks, "be a source of great satisfaction if it were possible to dispense with removal to hospital of cases of scarlet fever. There can, however, be little doubt that if this were done we should have a considerable increase of the disease, especially in poor and crowded households, the more so that in many instances the cases would be concealed. There is also little doubt that the type of the disease would be rendered more severe. It does not seem possible to contemplate such action. On the other hand, it is for the same reason not desirable to urge the removal of cases to hospital when isolation is being carried out at home in a suitable manner." Dr. Niven goes thoroughly into the behaviour of diphtheria in Manchester at the pre-school, school, and post-school age groups, and he concludes that aggregation in elementary schools plays a distinct though moderate part in the propagation of this disease. The incidence of the disease on the Manchester township has been within recent years materially less than in other parts of the city, and it is difficult to explain why the schools in the township should have escaped. The medical officer of health suggests that such relative immunity may be due to a process of immunisation from the spread of a bacillus of a comparatively low virulence which is able without causing disease to manufacture sufficient antitoxin to repel infection. There has been a gratifying decrease in the death-rate from enteric fever in Manchester during the last 20 years, the rate from 1901–05 having been 0·13 per 1000. The greatest incidence of the disease is in the fourth quarter of the year. As a general rule, and from a study of individual cases which was made in 1905, the conclusion was come to that a very large number of cases—no fewer than the number notified—are altogether overlooked. There can, we think, be little doubt that this is generally the case and that the remark has also application to certain other diseases. Dr. Niven does not regard it as probable that any material part of the autumnal rise is due to infected water or milk, and apparently, notwithstanding the investigations of Sidney Martin, of Horrocks, Firth, and others, he regards it as doubtful whether the enteric fever bacillus multiplies in the soil; he thinks it unlikely that the desiccation of excrement-polluted soil would suffice to may take place through a thick layer of skin and he recommended the injection of sterile solutions of this fluid by the Schleich method in order to render the deeper tissues accessible to the Finsen rays. Dr. Morvay has lately made a clinical trial of this method. He has treated 25 cases of lupus, scrofuloderma, tuberculous lymph glands, and skin cancer. A solution (0·1 to 1 per cent.) of erythrosin in sterile salt solution was injected as deeply as was necessary for the effect desired. In from two to five hours later the Finsen light was applied for from 15 to 20 minutes, or longer in the case of carcinoma. His experience fully confirms the claims made by Dreyer that in this manner the Finsen rays may be made to penetrate depths never before reached.

The Treatment of Chronic Interstitial Nephritis.

Dr. Révész of Nagyvárad has studied the effect of various measures upon chronic interstitial nephritis by the quantitative estimation of albumin and of the blood pressure. He came to the following conclusions. Warmth and carbonated baths diminish both albumin and blood pressure. The same holds true for rest in bed and inhalations of amyl nitrite. Exercise, especially climbing mountains, seems to have a very favourable influence; in normal individuals the pressure rises greatly, but in those afflicted with Bright's disease there is considerable dilatation of the vessels. The best results were obtained if the patients were allowed to exercise in the forenoon. Since albuminuria and increased arterial tension go hand in hand it is likely that interstitial nephritis is directly due to a narrowing of the afferent vessels of the kidney. Neurasthenia constitutes an important etiological factor and it would be a great mistake to condemn patients to muscular inactivity simply because they have a little serum albumin in their urine.

Sept. 29th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

An Institute Hospital.

THIS unique hospital is to be attached to the Rockefeller Institute for Medical Research in the city of New York. It will be devoted neither to charity nor to profit but solely to the advancement of the medical sciences. The primary object of the hospital is not the cure of the individual patient but to determine accurately the nature of certain features of his disease hitherto unknown. The incurable class and those suffering from new forms of disease will be preferred. It is proposed even to pay certain patients, suffering from diseases not well understood, for their attendance and submission to investigation. There will at times be a class of patients representing every phase of a disease, as cancer, tuberculosis, and pneumonia, in order that the conditions on which its progress depends may be studied with the most minute precision. The treatment, I am informed, will not be orthodox, that is, in accordance with rules now established in hospital practice, but will be governed by new truths disclosed, the object of this research being to discover new and more successful methods of combating disease. While old methods of treatment will necessarily be tested and their value accurately determined the real purpose of the investigators will be that of explorers—viz., to discover new facts on which will be based radical reforms in treatment. The cost of the structure will be $400,000. It will be an eight-storey building, with three floors of wards and a total capacity of 36 beds, and 12 single rooms reserved for individual maladies. Laboratories equipped for every kind of investigation will be provided. Professor Rufus I. Cole, of Johns Hopkins University, will be the head of the new hospital.

Oysters Guaranteed by the Board of Health.

Enteric fever from oysters containing the typhoid germs derived from the polluted waters where they are "fattened" for market has become so frequent that a new section has been added to the Sanitary Code of New York City. This section provides that oysters which have been "fattened" in polluted waters cannot be sold in the city; they must be brought direct from the ocean. The new law requires that every person who sells oysters in New York must have a written permit from the Board of Health. All applicants are required to give the names of the growers from whom they buy their stock and the location of the beds. The permits are revocable on proof that a dealer is selling "drinked oysters," as the dealers call oysters fattened in polluted waters. The adoption of this ordinance was the result of an inspection by officials of the Health Department of all the oyster beds situated between New Haven and New York and along the New Jersey coast. So frequently have outbreaks of enteric fever been traced to oysters that the people of the city had ceased to use them freely.

Popular Lectures on Tuberculosis by the Phonograph.

At each of the county fairs held during the autumn in the State of New York the State Charities Aid Association placed a tuberculosis exhibition together with a large talking machine to be used in connexion with the exhibition. The people hear a voice telling them that in this country 400 lives are daily sacrificed to the "Great White Plague" and that most of these deaths are entirely unnecessary; it explains in detail how the disease spreads and how it may be prevented; it teaches the value of fresh air and the necessity of ventilation and sunshine in every room in the home; and cleanliness and how to secure it are enforced with ample illustrations. The educational results of this simple method of instructing the common people have amply justified the innovation.

Conference on the Bubonic Plague.

The bubonic plague has become a well-grounded source of anxiety to the cities of the Pacific coast. San Francisco has for more than two years struggled to exterminate it but in vain. That prevention is safer, easier, and more economical than cure has been abundantly demonstrated in the experience of that city. Impressed by its example the health authority of the city of Tacoma, of the State of Washington, has issued invitations to all the health officers of the Pacific coast cities to attend a conference in Tacoma for a discussion of the plague and of the means of combating it. A number of health officers have signified their approval of the conference and their intention to attend.

The Fourth of July Celebrations: List of Injuries.

The *Journal of the American Medical Association* has published its sixth annual compilation of statistics of injuries occurring in the celebration of the Fourth of July in the United States. The total number was 5623. This is the largest number of injuries since the collection was first made in 1903. The total number of injuries for the six years under review is 29,296. Blank cartridges caused by far the larger number of injuries. The number of deaths was 163 in 1908 and 1316 for the six years. The fatality of the injuries has been reduced from 466 in 1903 to 163 in 1908, though the total number of injuries has been increased during that period from 4449 to 5623. The diminished fatality of these holiday injuries is probably due to the use of less dangerous explosives. The most interesting feature of these injuries is the complication of tetanus in the treatment of the wounds. There were 76 cases of tetanus this year, or three more than last year, but 13 less than in 1906. Since 1903 there has been a constant decrease until this year and this decrease of tetanus has kept pace with the decrease of cases of injury from blank cartridges. The usual site of injury in cases of tetanus was the hand and the blank cartridge was generally the weapon which inflicted the wound. Substitute and restrictive measures are now being adopted in the different States. Many cities limit the number and restrict the kinds of explosives, others limit the time of celebration, while a few prohibit fireworks except by officials. The annual publication of these statistics by which the public becomes informed of the dangers of what has been regarded as a harmless celebration of a national holiday will doubtless result in the prohibition of dangerous explosives and the substitution of harmless and more diverting methods of enjoyment.

Association of National Food and Dairy Departments.

One of the greatest defects in the operation of the "National Pure Food Law" is the want of coöperation of the national and the State authorities. The national and State standards differ and there is that lack of harmony which tends to neutralise the laws in their practical application, both national and State. The aim and purpose of the association are to secure such uniformity of requirements and interpretation as will furnish to the consuming public of every State alike ample and sufficient protection from fraud from diarrhœa, 38 from whooping-cough, 34 from measles, 34 from diphtheria, 29 from scarlet fever, and 23 from "fever" (principally enteric), but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·7 per 1000, corresponding with the rate that prevailed in the previous week; in London the death-rate from these diseases last week did not exceed 1·3. No death from any of these epidemic diseases was registered last week in Brighton, Plymouth, Wallasey, Northampton, King's Norton, West Hartlepool, or in Smethwick; whereas the annual death-rates therefrom ranged upwards in the other large towns to 3·7 in West Bromwich, 4·3 in Rhondda, 4·4 in Warrington, and 7·4 in Rotherham. The deaths attributed to diarrhœa in the 76 towns, which had steadily declined in the six preceding weeks from 1134 to 353, rose again under the influence of the remarkable increase of temperature to 363 in the week under notice, instead of showing a further decline; the highest annual death-rates from this cause last week were 3·0 in West Bromwich, 3·5 in Rhondda, 3·6 in Grimsby, and 4·9 in Rotherham. The 38 fatal cases of whooping-cough showed a decline of four from the number in the previous week; this disease caused the highest death-rates, 1·4 in Merthyr Tydfil and 1·6 in Walsall. The 34 deaths from measles showed, however, an increase of three, but caused death-rates equal to 1·5 both in Bootle and in Warrington. The fatal cases of diphtheria, which had been 43 and 39 in the two preceding weeks, further declined last week to 34, but included 15 in London and its suburban districts, and two each in Birmingham, Liverpool, Manchester, Hull, and Cardiff. The 29 deaths from scarlet fever exceeded by two the number in the previous week, including 14 in London and its suburban districts, eight in Liverpool and Bootle, and two in Manchester and Salford. Of the 23 deaths from "fever," showing a decline of 12 from the number in the previous week, nine occurred in London, and three both in Liverpool and in Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased from 2855 to 3467 in the four preceding weeks, had further risen to 3643 on Saturday, Oct. 3rd; the number of new cases of this disease admitted to these hospitals during the week under notice were 576, against 472, 625, and 565 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the four preceding weeks from 102 to 138, further rose to 159 in the week under notice, but were six below the corrected average number in the corresponding week of the five years 1903-07. The causes of 18, only 0·4 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were again duly certified in London, Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 53 other smaller towns during the week under notice; the 18 uncertified causes of death included two in Liverpool and two in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 14·4 and 13·5 per 1000 in the two preceding weeks, further declined to 13·4 in the week ending Oct. 3rd. During the 13 weeks of last quarter the annual death-rate in these eight towns averaged 13·8 per 1000 and exceeded by 0·4 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 3·0 and 9·8 in Perth and Paisley to 14·9 in Dundee and 15·2 in Edinburgh. The 474 deaths in the eight towns showed a further decline of one from the numbers returned in the two preceding weeks, and included 63 which were referred to the principal epidemic diseases, against numbers declining from 107 to 59 in the six preceding weeks; of these 63 deaths, 30 resulted from diarrhœa, 16 from whooping-cough, six from diphtheria, five from "fever," four from scarlet fever, and two from measles, but not one from small-pox. These 63 deaths were equal to an annual rate of 1·8 per 1000, exceeding by 0·1 the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had declined in the four preceding weeks from 64 to 35, further declined to 30 in the week under notice; 13 of these occurred in Glasgow, seven in Dundee, and three both in Edinburgh and in Leith. The fatal cases of whooping-cough, which had fallen in the four previous weeks from 19 to nine, rose again last week to 16, including 11 in Glasgow, three in Aberdeen, and two in Edinburgh. The six deaths from diphtheria were fewer by two than the number in the previous week; three occurred in Paisley and two in Gasgow. All the five deaths referred to "fever" were returned in Glasgow, three being certified as cerebro-spinal meningitis and two as enteric The fatal cases both of scarlet fever and of measles showed a slight increase; the four of scarlet fever included two in Edinburgh and two in Dundee. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 73 and 59 in the two previous weeks, rose again to 61 in the week under notice, but were four below the number returned in these towns in the corresponding week of last year. The causes of 19, or 4·0 per cent., of the deaths registered during the week in the eight towns were not certified or not stated; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·4 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·3 and 20·8 per 1000 in the two preceding weeks, declined again to 18·0 in the week ending Oct. 3rd. During the 13 weeks of last quarter the death-rate in Dublin averaged 19·9 per 1000; the mean rate during the same period did not exceed 12·5 in London and 12·9 in Edinburgh. The 136 deaths of Dublin residents during the week under notice showed a decline of 21 from the number returned in the previous week, and included 17 which were referred to the principal epidemic diseases, against numbers declining from 44 to 18 in the six preceding weeks. These 17 deaths were equal to an annual rate of 2·2 per 1000; the rate during the same week from these diseases did not exceed 1·3 in London and 1·2 in Edinburgh. Of the 17 deaths from these epidemic diseases in Dublin during last week, eight resulted from diarrhœa, four from "fever," four from measles, and one from scarlet fever, but not one from diphtheria, whooping-cough, or small-pox. The deaths attributed to diarrhœa, which had declined in the six preceding weeks from 39 to 12, further fell to eight last week. The four deaths referred to "fever" exceeded the numbers in recent weeks. The four fatal cases of measles corresponded with the number in the previous week; and the death from scarlet fever was the first registered since the beginning of August. The 136 deaths from all causes during the week included 25 of infants under one year of age and 38 of persons aged upwards of 60 years; the deaths of infants showed a marked decline from the numbers in recent weeks. Three inquest cases and two deaths from violence were registered; and 53, or 39·0 per cent., of the deaths occurred in public institutions. The causes of three, or 2·2 per cent., of the deaths registered in Dublin during the week were not certified; in London the causes of all the 1125 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was 2·9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881: Fleet-Surgeon Reginald Thomas Alexander Levinge has been placed on the retired list at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Oct. 3rd, 1908).

The following appointments are notified:—Fleet-Surgeons: T. Austen to the *Britannia* and J. Menary to the *Vengeance*, both on recommissioning. Surgeons: J. H. McDowall to the *Britannia*, on recommissioning; W. N. Horsfall to the *Pembroke*; and M. W. Haydon to the *Essex*.

ROYAL ARMY MEDICAL COLLEGE.

Lieutenant-Colonel Charles H. Melville, R.A.M.C., to be may take place through a thick layer of skin and he recommended the injection of sterile solutions of this fluid by the Schleich method in order to render the deeper tissues accessible to the Finsen rays. Dr. Morvay has lately made a clinical trial of this method. He has treated 25 cases of lupus, scrofuloderma, tuberculous lymph glands, and skin cancer. A solution (0·1 to 1 per cent.) of erythrosin in sterile salt solution was injected as deeply as was necessary for the effect desired. In from two to five hours later the Finsen light was applied for from 15 to 20 minutes, or longer in the case of carcinoma. His experience fully confirms the claims made by Dreyer that in this manner the Finsen rays may be made to penetrate depths never before reached.

The Treatment of Chronic Interstitial Nephritis.

Dr. Révész of Nagyvárad has studied the effect of various measures upon chronic interstitial nephritis by the quantitative estimation of albumin and of the blood pressure. He came to the following conclusions. Warmth and carbonated baths diminish both albumin and blood pressure. The same holds true for rest in bed and inhalations of amyl nitrite. Exercise, especially climbing mountains, seems to have a very favourable influence; in normal individuals the pressure rises greatly, but in those afflicted with Bright's disease there is considerable dilatation of the vessels. The best results were obtained if the patients were allowed to exercise in the forenoon. Since albuminuria and increased arterial tension go hand in hand it is likely that interstitial nephritis is directly due to a narrowing of the afferent vessels of the kidney. Neurasthenia constitutes an important etiological factor and it would be a great mistake to condemn patients to muscular inactivity simply because they have a little serum albumin in their urine.

Sept. 29th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

An Institute Hospital.

THIS unique hospital is to be attached to the Rockefeller Institute for Medical Research in the city of New York. It will be devoted neither to charity nor to profit but solely to the advancement of the medical sciences. The primary object of the hospital is not the cure of the individual patient but to determine accurately the nature of certain features of his disease hitherto unknown. The incurable class and those suffering from new forms of disease will be preferred. It is proposed even to pay certain patients, suffering from diseases not well understood, for their attendance and submission to investigation. There will at times be a class of patients representing every phase of a disease, as cancer, tuberculosis, and pneumonia, in order that the conditions on which its progress depends may be studied with the most minute precision. The treatment, I am informed, will not be orthodox, that is, in accordance with rules now established in hospital practice, but will be governed by new truths disclosed, the object of this research being to discover new and more successful methods of combating disease. While old methods of treatment will necessarily be tested and their value accurately determined the real purpose of the investigators will be that of explorers—viz., to discover new facts on which will be based radical reforms in treatment. The cost of the structure will be $400,000. It will be an eight-storey building, with three floors of wards and a total capacity of 36 beds, and 12 single rooms reserved for individual maladies. Laboratories equipped for every kind of investigation will be provided. Professor Rufus I. Cole, of Johns Hopkins University, will be the head of the new hospital.

Oysters Guaranteed by the Board of Health.

Enteric fever from oysters containing the typhoid germs derived from the polluted waters where they are "fattened" for market has become so frequent that a new section has been added to the Sanitary Code of New York City. This section provides that oysters which have been "fattened" in polluted waters cannot be sold in the city; they must be brought direct from the ocean. The new law requires that every person who sells oysters in New York must have a written permit from the Board of Health. All applicants are required to give the names of the growers from whom they buy their stock and the location of the beds. The permits are revocable on proof that a dealer is selling "drinked oysters," as the dealers call oysters fattened in polluted waters. The adoption of this ordinance was the result of an inspection by officials of the Health Department of all the oyster beds situated between New Haven and New York and along the New Jersey coast. So frequently have outbreaks of enteric fever been traced to oysters that the people of the city had ceased to use them freely.

Popular Lectures on Tuberculosis by the Phonograph.

At each of the county fairs held during the autumn in the State of New York the State Charities Aid Association placed a tuberculosis exhibition together with a large talking machine to be used in connexion with the exhibition. The people hear a voice telling them that in this country 400 lives are daily sacrificed to the "Great White Plague" and that most of these deaths are entirely unnecessary; it explains in detail how the disease spreads and how it may be prevented; it teaches the value of fresh air and the necessity of ventilation and sunshine in every room in the home; and cleanliness and how to secure it are enforced with ample illustrations. The educational results of this simple method of instructing the common people have amply justified the innovation.

Conference on the Bubonic Plague.

The bubonic plague has become a well-grounded source of anxiety to the cities of the Pacific coast. San Francisco has for more than two years struggled to exterminate it but in vain. That prevention is safer, easier, and more economical than cure has been abundantly demonstrated in the experience of that city. Impressed by its example the health authority of the city of Tacoma, of the State of Washington, has issued invitations to all the health officers of the Pacific coast cities to attend a conference in Tacoma for a discussion of the plague and of the means of combating it. A number of health officers have signified their approval of the conference and their intention to attend.

The Fourth of July Celebrations: List of Injuries.

The *Journal of the American Medical Association* has published its sixth annual compilation of statistics of injuries occurring in the celebration of the Fourth of July in the United States. The total number was 5623. This is the largest number of injuries since the collection was first made in 1903. The total number of injuries for the six years under review is 29,296. Blank cartridges caused by far the larger number of injuries. The number of deaths was 163 in 1908 and 1316 for the six years. The fatality of the injuries has been reduced from 466 in 1903 to 163 in 1908, though the total number of injuries has been increased during that period from 4449 to 5623. The diminished fatality of these holiday injuries is probably due to the use of less dangerous explosives. The most interesting feature of these injuries is the complication of tetanus in the treatment of the wounds. There were 76 cases of tetanus this year, or three more than last year, but 13 less than in 1906. Since 1903 there has been a constant decrease until this year and this decrease of tetanus has kept pace with the decrease of cases of injury from blank cartridges. The usual site of injury in cases of tetanus was the hand and the blank cartridge was generally the weapon which inflicted the wound. Substitute and restrictive measures are now being adopted in the different States. Many cities limit the number and restrict the kinds of explosives, others limit the time of celebration, while a few prohibit fireworks except by officials. The annual publication of these statistics by which the public becomes informed of the dangers of what has been regarded as a harmless celebration of a national holiday will doubtless result in the prohibition of dangerous explosives and the substitution of harmless and more diverting methods of enjoyment.

Association of National Food and Dairy Departments.

One of the greatest defects in the operation of the "National Pure Food Law" is the want of coöperation of the national and the State authorities. The national and State standards differ and there is that lack of harmony which tends to neutralise the laws in their practical application, both national and State. The aim and purpose of the association are to secure such uniformity of requirements and interpretation as will furnish to the consuming public of every State alike ample and sufficient protection from fraud otify changes of address of parochial patients suffering rom phthisis. Does this not portend the extension of otification soon to the whole of England? 3. In Scotand in 1906—that is, in a country where the mortality rom pulmonary tuberculosis has gone down 40 per cent., vhile in Ireland it has risen during the same period 20 per cent.—the Local Government Board issued a circular to the effect that the sections of the Public Health Act applicable o other infectious diseases are equally applicable to pulmonary phthisis and that the obligation resting on the local authority to deal with and control infectious disease extends to pulmonary phthisis. It is believed that Scotland will soon go for an Act making notification of phthisis (pulmonary tuberculosis) compulsory all over the country. With such examples, why can Ireland not be allowed (as through the genius and foresight of Her Excellency the Countess of Aberdeen she has taken a step in time in advance of these countries) to have notification of pulmonary tuberculosis applied to every part—urban or rural district?

Finally, Dr. McWalter says: "The fact that in 1864 the Irish death-rate from tuberculosis was the lowest in the three kingdoms, although no sanitary precautions were heard of, whereas now, after a quarter of a century's sanitary legislation, it is the highest, gives one to think furiously about the net result of these measures in actual practice." He should have also added that during the same period the English and Scotch rates have steadily fallen until now the death-rate from tuberculosis in England is 1·6 (1906), in Scotland 2·1 (1906), and in Ireland 2·7 (in both 1906 and 1907), and further that in all three countries typhus fever has declined, until in Ireland in 1907 there were only 56 deaths, while in 1869 there were 891 from this fever. Why, Sir, it is these very facts which are the cause of the agitation in Ireland which has culminated in Mr. Birrell's Bill.

1. We have not made the same progress in Ireland as in England or in Scotland in the sanitary measures taken to improve the dwellings of the people all over the country. 2. As pointed out in the report of the Belfast Health Commission in reference to the Births and Deaths Registration Act, "The absence of this (one of the provisions in the English and Scotch Bills) provision in Ireland has had the effect that no local authority appears to have the power of obtaining information which is of fundamental importance to them in their primary duty of searching for and coping with causes of ill-health and death among the population committed to their charge." As a result more is known in England and Scotland by the health authorities than in Ireland as to where the disease exists. 3. The difference between Ireland as compared with England and Scotland is that in the former far more patients are relieved medically at their homes under the Poor-law system which favours the treatment of even advanced cases at home. The tendency in England and Scotland is, under their Poor-law system, rather for more of such cases to be treated in institutions, such as union infirmaries, &c. As I have pointed out before,[1] Dr. Newsholme has, I believe, shown that typhus fever has been brought to the point of extinction by its institutional treatment, acting in conjunction with the removal of the motives for vagrancy. Phthisis has been rendered even more prevalent than formerly by increasing for this disease domestic at the expense of institutional treatment and by thus continuing the enormous number of domestic foci of this disease which are implied by the home medical treatment of phthisis among the poor.

In dealing with phthisis in Ireland we want (1) to know where the disease is and not alone where the deaths occur; (2) provision of hospitals, sanatoriums, and dispensaries for its treatment; (3) improvement in sanitary conditions; and (4) education of the people in the hygiene of the prevention of the disease. And it is because these are the main principles of Mr. Birrell's Bill that those (like myself) who have tried to do some work for their country in this anti-tuberculosis campaign hope it will pass.

I am, Sir, yours faithfully,

Oct. 5th, 1908.

JOHN BYERS.

PS.—Since writing this letter I see that the International Congress on Tuberculosis at Washington on Oct. 3rd (last Saturday) passed resolutions advocating the adoption by all Governments of compulsory notification of cases of tuberculosis.

To the Editor of THE LANCET.

SIR,—Let us see where we are. A Bill is before Parliament making the notification of tuberculosis compulsory in Ireland but not in England. I, as a humble member of a sanitary authority, venture to object to this special legislation. If Great Britain decides to adopt compulsory notification of phthisis, I am willing that Ireland be also included, but I object to penal legislation for one country more than another. I insist that no sufficient case has been made for exceptional treatment and that the statistics in Ireland are unreliable, as some 20 to 25 per cent. of deaths registered here are not certified by medical men. I have also hinted that although Lady Aberdeen's campaign seemed to favour compulsory notification, it should not be taken too seriously—that, in fact, it was not controlled by those representing the majority of the people.

My friend Dr. M. F. Cox takes me to task. Let me say that I consider him, with Dr. McWeeney and others, as altogether on the popular side, and as my masters in medical science, but I am unconvinced of their wisdom in this matter. Let us take, as my Lord Bacon would say, a crucial instance. Dr. Cox has probably one of the largest practices amongst consumptive patients in Ireland. He argues strongly that on every medical man should be imposed an obligation, enforceable by fine or imprisonment, to notify every case. Now for many years past the corporation of Dublin has begged practitioners to voluntarily notify cases of phthisis, in order that they might disinfect premises, &c. How many cases has Dr. Cox notified for the past five years? How many cases have all the Court physicians who now clamour to have their humbler brethren made common informers by Act of Parliament notified for the past five years? I venture to say not 2 per cent. of the entire number which they have attended, and I shall be glad to be corrected if I have understated the fact. Dr. Cox chides me for not repressing the discontent which is arising amongst public boards about this Tuberculosis Bill, but seriously I am gravelled for lack of argument, and I beg to be helped. It happens that I am the only medical practitioner on the various city public boards—the Dublin corporation, the Richmond Lunatic Asylum, and the North and South Dublin board of guardians—and I am called on to excuse or explain the action of the medical faculty to my colleagues whenever they find fault with it. What answer can I give as to why the doctors did not think it necessary to notify consumption voluntarily when begged to do so by the corporation, except in a few trivial cases, and why it becomes a matter of the gravest importance for the nation's weal to notify every case, provided a half-crown fee is attached by Parliament? Far be it from me to suggest that any of my medical brethren is influenced in the slightest degree by the fee, but I am only recounting a fact when I state that the public boards who are called on to pay the half-crowns contain many members who think otherwise, and that I find it almost impossible to persuade them to the contrary when they have practical experience that when the fee is paid cases are notified, and that when practitioners are asked to notify without fee in order that sanitary matters may be set right very few are found to do so, although surely the necessity is the same.

Dr. S. Agnew takes rather a broader view of the subject, but probably he will agree that in a country where no doctor attends some 24 per cent. of deathbeds it is futile to expect people to go to a physician and be booked as consumptives for the rest of their lives. Seriously, what are the sanitary authorities to do when you have notified a person as phthisical? If you tell us that a patient has typhus, typhoid, plague, or small-pox we are at least logical; we are prepared to provide for him with proper care in a hospital until he is well—or dead. But what are we to do with the consumptive? Of course, we can send him tracts about his disease, a nurse to advise him to keep open his windows, a sanitary inspector to look after his drains—but what of that? He will be dismissed from his employment; obviously, and as a principle of common law, you can compel no man to work or live with a certified consumptive. Shall we send them all to sanatoriums? If there are 100,000 in Ireland, as Lady Aberdeen's friends say, the cost, based on English experience public, the *Raises*, the Rajahs, and the Nawabs have many such philanthropic works to do for their poor brethren. It would have been better if the missionaries had preached the doctrine of sanitation with Christianity from the very outset. Urdu and Hindu papers ought to take up these subjects at least once or twice a month, either from English books or newspapers, to enlighten the general masses on these important subjects. The ryot and the *rais* ought to know that the labour and health of the poor are the wealth of the ryot.

---

[1] THE LANCET, Jan. 25th, 1908, p. 229.

Medical Relief in the Punjab.

In a Government resolution on the triennial report on the working of charitable dispensaries of the Punjab, it is mentioned that the Lieutenant-Governor has expressed the opinion that a large share of the financial resources of the province should in future be devoted to medical relief even, if necessary, at the expense of checking somewhat the rate of the progressive expenditure on higher education. If increased expenditure on any department is feasible the medical department is to have the first claim, but while saying this his honour does not fail to mention the desirability of private subscriptions being forthcoming. The citizens of certain districts have shown admirable public spirit in contributing to their hospitals, and now that arrangements have been made for enabling subscribers to earmark their subscriptions for particular objects and particular dispensaries each subscriber will be able to see for himself the good that he is doing for his fellow men, and it may be that the personal pride in an institution which he has helped to develop will open the purse-strings of many who have hesitated to give what has hitherto been really a mere donation to the funds of the district board, a body to which no particular sentiment can attach. The number of hospitals and dispensaries in the Punjab is steadily increasing, and they now total 425 as compared with 37 at the end of the last triennium, but there are plenty of districts where patients must travel long distances before they can obtain treatment. The number of in-patients is growing but it is thought that if all the dispensaries had beds for their patients and the hospital assistants were always popular with the people, the practice of indoor treatment would increase enormously. There were 3,750,000 of outdoor patients, which means a general increase on the previous three years, and evidently the system of medical relief is growing steadily in the confidence of the people. But though these public institutions can do so much, it is recognised that local bodies will never be able to provide medical assistance at every man's door, and it is hoped that unofficial doctors will step in and fill up the gaps. They will, it is anticipated, at first need protection against the charitable competition of public dispensaries, to which even the well-to-do resort unfairly for gratuitous medical relief, and still more a sympathetic backing from Government officials as a support to their prestige and reputation; but given this assistance there can be little doubt that the future extension of medical practice in rural tracts must be largely in the hands of the private practitioners.

Births and Deaths in Eastern Bengal.

It is difficult to assign any definite cause for a steady and continuous fall in the birth-rate over a large area, such, for example, as is recorded for 10 out of 14 districts in Eastern Bengal during the past year, and which was noticed in 1906, remarks a contemporary. The decrease during the past two years has been most pronounced in the Backergunj, Dinajpur, Tipperah, Mymensingh, and Dacca districts. In Rungpur and Malda alone has the birth-rate been steady, while in only two districts, Chittagong and Jalpaiguri, has there been any marked rise. "It is impossible to say," writes the Sanitary Commissioner, "what the significance of this fall in the birth-rate may be; but it is interesting to note that Chittagong and Jalpaiguri are the two districts which have been least affected by scarcity. There is no evidence that it is due to any widespread defect in reporting." The death-rate in Eastern Bengal last year fell from 31·67 in 1906 to 29·30 per 1000, the past year, on the whole, having been a healthy one.

Surgical Equipment in the United Province Hospitals.

One of the directions in which increased efficiency is especially noticeable in the medical department of the United Provinces is in connexion with the surgical operations.

Colonel R. D. Murray, I.M.S., Inspector-General of Civil Hospitals in the United Provinces, remarks that the advance in the number of operations combined with the increase in the number of patients cured by them is a matter of congratulation. He proceeds: "It is due in large measures not only to the increasing confidence of the people and to the extended scope which medical officers enjoy under modern surgical procedure but also to the stimulus which has been given to operative work by the improvement to operating rooms and surgical equipment during the past few years. My predecessor, Colonel Joubert, commenced a campaign against obsolete instruments and obsolete methods which is now beginning to bear fruit, and I have done my best to continue the good work by building new operating rooms and removing defects from old ones wherever it has been possible. There is hardly an operating room in these provinces which has not been either rebuilt or remodelled during the past three years, or for which structural alterations have not been proposed. My work in this direction has unfortunately been stopped temporarily by the necessities of the existing famine, and all projects are in abeyance. Operations are now possible in our larger hospitals which a few years ago were not undertaken at all or, if so, with the greatest apprehension. The triumphs of modern surgery can only be achieved by attention to that complete asepsis which can alone insure success and which was impossible under the old conditions. Not only civil surgeons but assistant surgeons undertake formidable abdominal and other operations with success which formerly were precluded on account of the dirty surroundings under which they had to be performed."

Sept. 15th.

NEW ZEALAND.

(From our own Correspondent.)

Ambulance Lectures.

Many of the medical men here have felt lately that the giving of lectures on first aid and ambulance work should be paid either by the local authorities or by the Government. Some discussion has taken place in the newspapers on this point. It has not been suggested that lectures to the general public should be paid for, but that whenever police, tramway officials, and so on, have to be instructed some monetary recompense should be made to the medical instructors. There is a considerable measure of justice in the request. Many employers, steamship companies, railways, mines, and the like, require that anyone seeking admission to their services must give evidence of a knowledge of first aid. There would seem to be no just reason that medical men should supply this education free of charge.

Sanitary Corps.

Following the example of our Eastern teachers the Defence Council here, on the suggestion of Surgeon-General Skerman and the Hon. Colonel Collins, set up a sanitary branch of our little army. The chief health officer (Dr. J. M. Mason) at the request of the council delivered a series of lectures on military hygiene, which were well attended, not only by the medical staff, but by the combatant branch of the service. A schedule has been issued with new regulations which have been adopted by the Defence Council with respect to the New Zealand Medical Corps, which deals *inter alia* with the sanitary branch of the service. The chief sanitary officer is attached to the Surgeon-General's staff and his duty will be to see that proper provision is made so that the principal medical officers in their several districts will have at their disposal sanitary experts who will advise them as to the best site for camps, the sanitary condition of our forts, water-supply, &c. Dr. Mason has been appointed chief sanitary officer with the rank of lieutenant-colonel. Attached to the health department are a large number of specially qualified experts, and the idea is to utilise their knowledge in military matters as well as in that which concerns the health of the general community.

Appointment of Mr. J. A. Gilruth.

To the great regret of all who value original research Mr. J. A. Gilruth, M.R.C.V.S., has been induced to leave this country for fresh work in Victoria. For long Mr.

was nothing visible, red and white blood corpuscles being conspicuous by their absence. The final examination was conducted on August 5th when, apart from any marked alteration in the character of the physical signs, the urine was found to be normal, in colour pale amber tint, reaction acid with litmus as indicator, specific gravity 1022, no albumin, no deposit, but just a trace of mucus in suspension, as is commonly observed in the case of healthy individuals.

The points of interest are *these*:—1. *The comparative* length of time that elapsed before symptoms manifested themselves (12 hours). This may be accounted for in part by the character of the preparation used, the proportion of the active ingredient in the plaster being 1 in 3 approximately and in the liquor 1 in 2. The personal factor has likewise to be taken into consideration, patients varying, no doubt, in their susceptibility to the influence of the drug. In this direction it is of interest to recall certain observations made by Christison in dealing with the subject of poisoning by cantharides. He remarks that "it is probable that this is one of the poisons whose operation is liable to be materially affected by idiosyncrasy. The medical dose is from ½ gr. to 2 grs. of the powder, and from 10 drops to 2 drs.[2] of the tincture. But Dr. Beck has quoted an instance where 6 ozs. of the tincture were taken without injury. On the other hand, Werlhoff has mentioned the case of a lad who used to be attacked with erection and involuntary emission on merely smelling the powder." This statement, adds Christison, though extraordinary, is not without support from the parallel effects of other substances. 2. Absence of symptoms due to the manner in which the drug is excreted by the gastro-intestinal mucous membrane; there was neither vomiting nor diarrhœa; indeed, it was necessary to administer purgatives before the bowels could be induced to act. 3. Absence of symptoms referable to the genital organs; no heat, no pain, tenderness, or swelling of the parts having been observed, and no spermatozoa having been detected in the urinary sediment, though looked for on several occasions. Christison remarks that whilst "a great number of cases are on record, but few have been minutely related. Sometimes cantharides have been swallowed for the purpose of self-destruction, sometimes for procuring miscarriage; but most frequently on account of a prevalent notion that it possesses aphrodisiac properties, it has been both voluntarily swallowed and secretly administered to excite the venereal appetite. That it has this effect in many instances cannot be doubted. But the old stories which have been the cause of its being so frequently used for the purpose are many of them fabulous and all exaggerated. Often no venereal appetite is excited, sometimes even no affection of the urinary or genital organs at all, and the kidneys and bladder may be powerfully affected without the genital organs participating. It is established, too, by frequent observation that the excitement of the genital organs can never be induced without other violent constitutional symptoms being also brought on to the great hazard of life."

The patient is convalescent at the present time, a natural cure having been effected by resorption of the pleural exudate. The urine is quite normal. In conclusion, I beg to state my indebtedness to Dr. Currie for permission to publish brief notes on the case.

I am, Sir, yours faithfully,
J. STANLEY AVERY, M.B., B.S. Lond.,
House Physician, Johannesburg Hospital.

THE TREATMENT OF INOPERABLE CANCER.

To the Editor of THE LANCET.

SIR,—In his most interesting paper on this subject in THE LANCET of Oct. 3rd, p. 997, Mr. Henry Morris does not refer to the advisability of the systematic examination of the blood. It is a matter of common knowledge that the white corpuscles are increased in number and altered in relative proportion to each other. At the same time the red cells are as a rule diminished. It would appear that in these facts there is to be found a starting point capable of being used in the investigation of possible remedies and one to which sufficient attention has not yet been given. It is reasonable to suppose that if the definite change in the blood which occurs in all cases of advanced cancer can be rectified a cure may result. A systematic and thorough investigation of the condition of the blood cells, especially of the white, carried out during any form of experimental treatment at any of the institutions specially devoted to the treatment of cancer would probably give most valuable information. By our treatment the red cells quickly increase to normal or over, but it is much more difficult to reduce the number of the white corpuscles to the average of health.

We are, Sir, yours faithfully,
SKENE KEITH,
GEO. E. KEITH.
Upper Berkeley-street, Portman-square, W., Oct. 5th, 1903.

AN OPERATION FOR PARAPHIMOSIS.

To the Editor of THE LANCET.

SIR,—I shall be grateful if you will allow me to bring before your readers the following procedure in cases of paraphimosis. 1. An annular incision is made through the mucous membrane of the foreskin a quarter of an inch from its reflection from the glans penis; this incision reaches down to the submucous plane. 2. A second annular incision is made through the skin of the penis half an inch from the mucocutaneous junction; this incision reaches down to the subcutaneous plane. 3. A sagittal incision is made along the dorsum connecting the two annular incisions and as before reaching down to the submucous-subcutaneous planes. 4. The collar of tissue thus marked out is peeled off in the above plane. 5. All bleeding vessels are secured and tied with catgut. 6. The cut edges of the skin and mucous membrane are approximated by a series of discontinuous catgut sutures.

The following points illustrate the advantages of this method: 1. Reduction in old-standing cases can at the best only be performed (*a*) by the exercise of much force and with considerable pain to the patient; or (*b*) "the narrow constricting band caused by the orifice of the prepuce must be divided on the dorsal aspect. This will free the parts which can be subsequently drawn forwards, and after the œdema has been reduced by applying lotio plumbi for a few days circumcision may be advantageously undertaken" (Rose and Carless). 2. Circumcision at a later date is generally advisable, thus necessitating delay and a second anæsthetic. 3. The operation can be safely undertaken, even in these cases where local destruction of tissue has resulted from pressure.

I am, Sir, yours faithfully,
G. H. DIVE, M.R.C.S. Eng.
St. Bartholomew's Hospital, Sept. 30th, 1903.

THE MEDICAL AUTHORSHIP OF THE THIRD GOSPEL.

To the Editor of THE LANCET.

SIR,—In an annotation in THE LANCET of Sept. 26th you adduce strong evidence to prove that both the Third Gospel and the Acts of the Apostles were written by St. Luke. Incidentally I think this fact affords a proof that the Second Gospel was written by St. Mark. In Paul's first journey with Barnabas they were accompanied by Mark, who left them on the way, and as Paul himself said "went not with them to the work." When they proposed a second journey Paul objected so strongly to Mark accompanying them that he and Barnabas parted and Mark accompanied Barnabas whilst Paul selected Silas as a companion. For some unassigned reason Silas appears to have ceased to be Paul's companion and his place was taken by Luke who accompanied Paul on his last journeys. It would be only natural that Mark should retain some of the ill feeling which arose during the strife between Barnabas and Paul about him and should include also Paul's companion Luke. It is curious to note that while St. Luke simply mentions the case "of a woman having an issue of blood 12 years, which had spent all her living upon physicians and neither could be healed by any," Mark says, "She suffered many things from many physicians but was nothing better but rather grew worse." In this expression there appears a certain amount of bitterness against the profession to which St. Luke belonged, and which, if hardly to be expected from an evangelist, was nevertheless entirely human, and I

[2] The present official dose of the tincture of cantharides is from 5 to 15 minims, or from 2 to 5 minims if used repeatedly.—ED. L.

Obstetrical Section of the Royal Academy of Medicine in Ireland, the presidency of the British Gynæcological Society, and the presidency of the Obstetrical Section of the International Medical Congress—on the occasion of the triennial meeting at Berlin in 1890. His grasp, mental and moral, as a lecturer and teacher as well as practitioner and administrator, was characterised by the emphatic stamp of his physical vigour.

Sir Arthur Macan's death has left a conspicuous blank in the phalanx of Irish gynæcologists and is universally deplored. His remarkable physique had been showing signs of failure for some months and decline of cardiac vigour hastened the end. His valuable published contributions include papers on his specialty in the *Transactions of the Royal Academy of Medicine in Ireland* and other professional periodicals. He also translated the "Intestinal Parasites" of Professor Heller.

ROBERT NIVEN, M.D., CH.B. GLASG., D.P.H. CAMB.

Dr. Robert Niven, medical superintendent of the West Ham Infirmary, Whipps Cross, Leytonstone, died there on Wednesday, Sept. 23rd, at the early age of 32 years. Dr. Niven had held the position of superintendent for just 12 months. He received his medical education at the University of Glasgow, where he graduated M.B., Ch.B. (commend.) in 1898 and M.D. in 1905. Immediately after graduation he was appointed junior house surgeon to the West Ham and East London Hospital, in due course becoming senior house surgeon there. He next went to Bethnall House Lunatic Asylum, where, in addition to obtaining lunacy experience, he worked at the London Hospital for the D.P.H. Camb., which he took in 1901. His next appointment was that of assistant medical officer at the South-Western Fever Hospital, Stockwell. During the late small-pox epidemic he went to Gore Farm Hospital where his devotion to duty was recognised by the Metropolitan Asylums Board by a special letter of thanks and an honorarium. Afterwards he obtained the appointment of senior assistant medical officer at the Camberwell Infirmary which he held till he went to West Ham a year ago. At West Ham Infirmary, where matters had been in a somewhat unsettled state for some time, his firm discipline and excellent administrative ability soon showed themselves and he displayed great energy in carrying out the duties of his responsible position. Among other things he undertook the reorganisation of the nursing staff and proved a strict disciplinarian, upholding the rules of the institution to the letter. Unfortunately his health broke down soon after he entered on his duties and he had to go first to the King's Sanatorium and afterwards to Switzerland suffering from a tuberculous affection of the right lung. At the end of three months he came back very much improved in health and took up his duties with renewed zest. The lung trouble had become quiescent, but unfortunately about a fortnight ago he developed influenza and an attack of croupous pneumonia supervened which terminated a useful and promising career. Dr. Niven will be greatly missed.

ALFRED CHARLES FESTING SMITH, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,

MEDICAL OFFICER IN CHARGE OF TROOPS, BULL POINT, DEVONPORT.

Mr. A. C. Festing Smith died suddenly at St. Budeaux (Cornwall) on Sept. 25th, from syncope, whilst visiting a patient. The deceased, who was in his fortieth year, was the younger son of the late Commander G. T. C. Smith, R.N., of Rathmullen, Ireland. He received his medical education at Queen's College, Cork, and qualified L.R.C.P. & S. Edin. and L.F.P.S. Glasg. in 1891. After holding a resident appointment at the Royal Albert Hospital, Devonport, Mr. Smith, about 12 years ago, commenced practice at St. Budeaux when he soon became highly popular. He was surgeon in charge of the troops at Bull Point, Devonport. Mr. Smith was formerly an alderman of the Devonport town council but had recently resigned the office. He had been overworked lately and this year had not been able to have his usual summer holiday. He married the eldest daughter of Lord Kinsale, who, with three children, is left to mourn his death.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Salomon Neumann of Berlin, at the age 88. He was born in Pyritz and studied medicine Halle, where he was one of Professor Peter Kruk berg's most distinguished pupils. He collected medi statistics and wrote numerous papers on sanitary subje which attracted the attention of the civic authorities Berlin where he practised so that he was appointed member of the city council and this post gave him abunda opportunities of continuing his statistical and other r searches. He did not give up his work until some 13 yea ago when advancing age compelled him to retire. F many years he worked in conjunction with Professor Rudol Virchow, the two being great personal friends.—Dr. Juliu Laudenbach, professor of pharmacology in the University o Kieff.—Dr. Edouard Rondot, formerly *agrégé* in the Uni versity of Bordeaux and medical officer to the hospitals o that city.—Dr. B. Florschütz of Wiesbaden, the eminent archæologist, at the age of 70 years.

Medical News.

Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England.—At the first professional examination of the Conjoint Examining Board, held on Sept. 29th and 30th and Oct. 1st and 2nd, the following gentlemen were approved in the subjects indicated below:—

Chemistry and Physics.—John Vere Orlebar Andrew, Brighton Technical College; Fritz Ernest Bendix, West Ham Municipal Technical Institute; Frank Rex Fletcher, London Hospital; Frank Cane Godding, Guy's Hospital; Ralph Jones, Charing Cross Hospital; Charles Virgil Nunez Lyne, Birkbeck College; Percy Uvedale Mawer and Frederick Meinertzhagen, St. Bartholomew's Hospital; Frank Andrew Miller Nelson, London Hospital; Aly Heidar Taymour, Cairo and Guy's Hospital; and Clement Arthur Webster, Manchester University.

Chemistry.—Stephen Leonard Baker, London Hospital; John Henry Bennett, St. George's Hospital; Cyril Amand Bernard, Liverpool University; Bertram James Brewitt, St. Bartholemew's Hospital; Sydney Hudson Keys, Birkbeck College; Claude Kingston, University College, Bristol; William Arthur Rail, Melbourne University and St. Bartholomew's Hospital; and George Sydney Stathers, Cambridge University and University College Hospital.

Physics.—Robert Graham Brown, London Hospital; Arthur Geoffrey Morris, University College, Bristol; William Morris and Henry Barton Owens, London Hospital; Frederic Simpson, Charing Cross Hospital; and Lindsay Olive Smith, London Hospital.

Biology.—Robert Graham Brown and John Lyon, London Hospital; Horace Mather, Guy's Hospitals; Arthur Wellington Matthew and Henry Felix Mullan, London Hospital; John Hunter Pugh, Guy's Hospital; Philip Pennefather Warren, London Hospital; and Gerald Charles Wright, London Hospital.

Royal College of Surgeons of England.—At the Preliminary Science Examination for the Licence in Dental Surgery of the Royal College of Surgeons of England the following gentlemen were approved in the subjects indicated:—

. eslie Miller, Charing Cross Hospital Birkbeck College; and Richard Reginald College.

Chemistry.—Sidney Roland Bacon, Charing Cross Hospital; Chandulal Manilal Desai, Guy's Hospital; Denis Foster Lewis, Birmingham University; Frederic Winbolt Lewis, Middlesex Hospital; and Whalley Seath Stranack, University College Hospital.

Physics.—John Eric Rhys Evans, Guy's Hospital; Carl Joseph Oldham Jensen, Charing Cross Hospital; Richard Angwin Rail, South African College, Cape Town; and John Fitzgerald Williamson, Charing Cross Hospital.

The London Medical Exhibition.—Proof of the interest taken by the members of the medical profession in this annual exhibition is furnished by the increased attendances shown year by year. The fourth meeting was held under excellent auspices this week at the Royal Horticultural Hall, Vincent-square, Westminster, the opening ceremony taking place on Monday, Oct. 5th, the exhibition remaining open until Friday, the 9th. The organising committee adopted the plan of excluding so far as was possible the lay visitor, and success appears to have attended the scheme, since it was quite obvious that in the main the surgeon and the physician were in attendance. The exhibits were very tastefully arranged and for the most part came well within the purview of medical matters. In a future issue we hope to give an account of certain of the exhibits that some idea may be gained of what may be regarded to be the latest developments concerning drugs, foods, surgical appliances, and so forth.

surgeon in attendance. Early and extensive operation was necessary if the symptoms pointed to the presence of a tumour.

Dr. MacCosh (New York) brought forward a case of Sarcoma of the Spinal Cord removed by operation. The patient was alive and well six years later. The laminæ and spines of three dorsal vertebræ were removed but the patient's back had not been materially weakened.

Hernia.

Dr. William Sheen (Cardiff) contributed a paper on the Etiology of Hernia. He discussed it from the medico-legal standpoint and showed that the sudden development of hernia was clinical and not pathological, for the sac must have been already present since the sudden formation of a sac with its contents is impossible.

A discussion on the Radical Cure of Inguinal Hernia was opened by Dr. R. Alessandri (Rome). In his paper he laid down the essentials of the operation. They were: (1) the excision of the sac as high as possible without leaving any depression in the peritoneal wall; and (2) the formation of a complete and firm wall. After an examination of the various procedures he described in detail Bassini's method, and mentioned the variations for the different forms of inguinal hernia; and lastly, he discussed the question of the material for the sutures, and the length of duration of rest required after the operation.

Dr. Petrovitch (Nisch) had operated on 7000 cases of inguinal hernia during the last ten years in Servia. His patients were militiamen who remained under observation for from one year to eighteen months afterwards. His mortality was 0·13 per cent.; recurrences, 0·6 per cent.; and a good result in 98·85 per cent. Bassini's method was employed 1002 times, Kocher's in 266 cases. One method did not seem better than the other.

Dr. Subbotitch (Belgrade) gave an account of his method of treating the sac in those difficult cases where it could not be readily separated from the spermatic cord.

Dr. Vanverts (Lille) stated that he secured the pedicle of the sac with sutures but did not necessarily remove it.

Dr. Hildebrand (Berlin) described the operative treatment of femoral hernia, which was further discussed by Dr. Lotheissen, Dr. Léon Bérard (Lyons), and Dr. Vanverts.

Professor Fraenkel (Berlin) read a report on Umbilical Hernia, whilst Dr. Lothioir (Brussels), and Dr. Nové-Josserand (Lyons) dealt with Hernia in Children.

Professor Kallionitzis (Athens) and Dr. Verhoef (Bruges) agreed that Bassini's operation was the best method of securing a radical cure of inguinal hernia.

Entertainments.

It appears to be necessary to infuse a certain amount of gaiety into every congress, even when the meeting is taken as seriously as has become the custom at the International Society of Surgery. The executive committee at Brussels made every preparation to enable the members to enjoy themselves, whilst a ladies committee, under the management of Madame Depage and Madame Lothioir, made such excellent arrangements that their guests saw many of the beautiful outskirts of Brussels with the least possible degree of fatigue. The public entertainments consisted of an evening reception by the Belgian Society of Surgery at the Cercle Artistique et Littéraire; a reception by Professor Czerny, President of the Congress, in the beautiful house of Dr. Depage; a gala performance at the Théâtre Royal de la Monnaie; and a reception at the Hôtel de Ville, where the vast suite of rooms was seen to perfection. There were also most charming drives to the Bois de Cambre and to the golf club at Tervueren, two of the prettiest suburbs of Brussels. But these public entertainments were thrown into the shade by the lavish private hospitality extended to every member of the Congress, a hospitality which allowed of the formation of many new friendships and the cementing and renewal of many old ones. By such means the members of the great medical profession throughout the world become truly fraternal; individuality remains owing to the barriers of language and upbringing, but constant association gives such a knowledge of each other's peculiarities as to lead to no greater amount of friction than occurs in every large family. Madame Depage, Madame Lothioir, and Madame Willems may therefore rest assured that their efforts will have a great and lasting effect upon the social aspect of European surgery.

The public banquet was held in the hall of La Grande Harmonie and was attended by more than 220 guests. Professor Czerny was in the chair and at the high table were M. De Met, Burgomaster of Brussels; M. Velghe, representing the Minister of Agriculture; the Prince de Reuss, Secretary of the German Legation; Professor Lucas-Championnière; with Madame Sonnenberg, Mrs. D'Arcy Power, and Madame Hartmann. Professor Czerny proposed in French the toast of "The Organising Committee at Brussels," and after translating his speech into German terminated it with "Vive le Roi des Belges! Vive l'Empereur d'Allemagne." M. Velghe drank to the health of those members of the Congress who had come from abroad; to the Governments who had sent representatives; and to the success of the next Congress. M. Segonel proposed the abstract toast of "The Beautiful Flowers which Decorated the Tables" and coupled with it that of the ladies who had come from all parts to grace the meeting and to add pleasure, beauty, and freshness to the Congress. The toast was received with the greatest cordiality and with the "good fire" characteristic of a French gathering. The banquet was followed by some excellent music and minuet dancing.

The General Meeting.

The general meeting was held on Wednesday afternoon, Sept. 23rd, and was preceded by a meeting of the international committee. It was agreed that the next meeting should be held at Brussels in 1911. Professor Lucas-Championnière of Paris was unanimously elected president; Dr. Lothioir, of Brussels, treasurer; and Dr. Depage and Dr. L. Meyer, also of Brussels, secretaries. Three subjects were chosen for discussion in 1911: (1) The Surgery of the Lung; (2) The Causes and Treatment of Colitis; and (3) The Causes and Treatment of Pancreatitis. At a meeting of the English members present at the Congress Mr. D'Arcy Power, Mr. J. Paul Bush, and Sir William Macewen were chosen to form the national committee for Great Britain and Ireland until the next congress, the senior member to act as a member of the international committee. The national committee was desired to make every effort to enlist the sympathy of English surgeons in the society and to prevent, if possible, such an inadequate representation of British surgery as had occurred on the present occasion.

Conclusions.

The most striking features at the present Congress were the results of the discussion on Cancer and the magnificent exhibition of specimens due to the disease. From all sides, from clinical experience, statistics, maps, from museum specimens, and from the interchange of opinions, it seemed clear that malignant disease was locally infective, certainly to the individual, perhaps in some modified form from one person to another. There appears to be a latent knowledge of its cause which only awaits a keen observer or a fortunate experiment to make clear. The general trend of surgical opinion was against extensive operations and in favour of early treatment with thorough removal whilst the disease was still local. This, however, is only possible when public opinion sets towards early diagnosis. It is hampered at present by the idea that cancer is a painful disease and that because a lump is not painful it cannot be dangerous. In some parts of Austria women and medical practitioners alike have been taught not to disregard the first signs of uterine disturbance at the time of the menopause. The result is shown in the wonderful display of specimens of cancer of the cervix which were exhibited at Brussels, many of the preparations being in a much earlier stage of the disease than is ever seen in this country. It is possible therefore to educate the public until it no longer waits for advanced signs of the disease with implication of lymphatic glands and the neighbouring structures.

It seemed clear that the surgery of the liver was in a less advanced stage than the surgery of cancer. It is evident that comparatively little care is taken in the matter of diagnosis until pain or very obvious signs, often of long standing, compel the patient to seek surgical assistance. The mortality after operations on the liver, therefore, is still unduly high, because exploration of the liver too often shows an extensive inflammation which in the earlier stages might have been remedied with very little danger.

The discussion on anæsthesia brought out the fact that the English-speaking nations are still in advance of their European colleagues in the safe production of general

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Dimock, Horace, M.B., B.C. Cantab., [illegible] been appointed Resident Anæsthetist [illegible]

Fowler, T. Webb, M.D., Ch.B. Birm., [illegible] has been appointed Honorary Medi[illegible] Warwickshire Hospital.

Gleed, Seymour R., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Hospital for Women, Brighton.

Howse, Arthur Edward, M.R.C.S., L.S.A., has been appointed District Medical Officer by the Frome (Somerset) Board of Guardians.

Hulbert, H. L. P., M.B., B.S., D.P.H. Camb., has been appointed School Medical Officer to the Northamptonshire Education Committee.

Jeans, Frank A. G., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Royal Infirmary, Liverpool.

Paterson, Alexander S., M.B., Ch.B. Edin., has been appointed House Physician at the Salford Royal Hospital.

Peek, J. H., M.B., Ch.B. Edin., has been appointed Resident Surgeon at Ramsgate General Hospital and Visiting Surgeon to the St. Lawrence Dispensary.

Roderick, H. B., M.D., B.S. Cantab., has been reappointed Demonstrator of Surgery in the University of Cambridge.

Sachs, Alfred L., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Queen's Hospital for Children, Finchley road, N.W.

Taylor, Stuart Hopcraft [illegible] appointed District Medical [illegible] of Guardians.

Tolputt, Percy Thomas, L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer by the Pembroke Board of Guardians.

Woodforde, G. A. W., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Junior Resident Medical Officer at Queen Charlotte's Hospital.

Wrigley, Philip Roscoe, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Surgeon to the Salford Royal Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bath, Royal Mineral Water Hospital.—Resident Medical Officer. Salary £100, with board, lodging, and laundry.

Birmingham General Dispensary.—Resident Surgeons, unmarried. Salary £170 per annum, and rooms, fire, lights, and attendance.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with board, apartments, and attendance.

Bradford Children's Hospital.—House Surgeon. Salary £100.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodging.

Brighton, Sussex County Hospital.—House Surgeon, unmarried. Salary £120 per annum, with board and residence. Also Second House Surgeon, unmarried. Salary £60 per annum, with apartments, board, and laundry.

Bristol General Hospital.—Casualty House Surgeon. Salary £60 per annum, with board, residence, &c.

Bristol [illegible] Salar[illegible]

Buxton, [illegible] geon.

Carlisle [illegible] Westmorland Asylum, Garlands.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, rising to £150, with board and lodging.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £120 per annum, with board, &c.

Dudley, Guest Hospital.—Assistant House Surgeon. Salary £60 per annum, [illegible]

Dumfries [illegible].—Assistant House Surgeon. S[illegible] and lodging.

General Infirmary at Gloucester and the Gloucestershire Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing. Also [illegible] Physician.

Gillingham (Kent) Education Committee.—School Medical Officer. Salary at rate of £250 per annum, rising to £300.

Grimsby and District Hospital.—House Surgeon. Salary £120 per annum, with board, lodging, attendance, and washing.

Guildford, Royal Surrey County Hospital.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Halifax Union Poor-law Hospital.—Resident Medical Officer. Salary £110 per annum, with apartments, rations, and washing.

Hampstead General Hospital.—Physician to Out-patients, Surgeon to Out-patients, and Ophthalmic Surgeon to Out-patients.

Homes for Little Boys, Farningham and Swanley, Kent.—Medical Officer, unmarried. Salary £100 per annum, with board, residence, and laundry.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Physician and House Surgeon for six months. Salaries £30, with board and residence. Also Assistant Casualty Medical Officer for six months. Salary £20, with board and residence.

Hospital for Epilepsy and Paralysis and Other Diseases of the Nervous System, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

Hospital for Women, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £60 per annum.

Ipswich, East Suffolk and Ipswich Hospital.—House Surgeon for six months. Salary at rate of £65 per annum.

Kettering and District General Hospital.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, residence, &c.

Lancaster, Royal Lancaster Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

Leeds, Hospital for Women and Children.—House Surgeon. Salary at rate of £50 per annum, with board.

Leeds Public Dispensary.—Two Resident Medical Officers. Salary £100 per annum, with board and lodging.

Leyton, Walthamstow, and Wanstead Children's and General Hospital.—Resident House Surgeon. Salary £100 per annum, with [illegible]

Liv[illegible].—Assistant Medical Officer. [illegible] per annum,

London Lock Hospital, Dean-street, W.—Anæsthetist to the Male Hospital.

Margate, Royal Sea Bathing Hospital.—Resident Surgeon, as Junior and later as Senior. Salary at rate of £80 and £120 per annum respectively, with board and residence.

hills must be, in any case, some score of miles away. Those on the west of the line form the curiously jagged volcanic range known as the Harra, while on the east is a low range, in which rises a strangely shaped rock, not unlike a gigantic Moslem pulpit in form, and consequently called by the Arabs the *Munbir-er-Rasul*, or Pulpit of the Prophet. The yield of the spring is very abundant; we endeavoured to make a rough estimate of it by the "weir" method and found that it was then producing over 600 tons in the 24 hours. The possible error of calculation in such an observation (which was of necessity carried out in a rather primitive manner) is considerable, but the yield is in any case very great, and Meissner Pasha informs me that, though it had never before been measured, the yield is certainly over 400 tons per day.

Three wells have been sunk close to the station at Tebuk. The principal one is at the station; it has a diameter of about three metres and a depth of 22·80 metres to the surface of the water. The depth of the water was only half a metre at the side and one metre in the middle. As at Ma'an, a steam pump, with windmill in reserve, has been put up by the well, and raises the water to two large reservoirs on a water-tower. This well yields as much as 400 tons of water per day. The two other wells are situated respectively 150 and 250 metres to the west of the station; they are not provided with pumps, and their yield is not known. We were informed by several persons that an abundant supply of water is found in the plain of Tebuk wherever a well is sunk, and that there is probably a continuous and practically inexhaustible underground layer of water here. On the other hand, Meissner Pasha has some doubts as to the accuracy of this statement. The first well sunk by the railway authorities, he tells me, gave relatively unsatisfactory results, and he thinks that the water exists in all probability in the form of separate underground streams rather than as a continuous layer ("*des veines d'eau plutôt qu'une nappe souterraine*"). At all events, all are agreed that the subterranean water here is in movement and that that movement is towards the west (no doubt towards the Gulf of Akaba and the Red Sea). The importance of this fact is obvious, in connexion with the questions of providing the future lazaret with water and the disposal of the sewage matter of the lazaret without contaminating that water. With regard to the latter point, it is clear that the sewage matter will have to be disposed of well to the west of the lazaret site, particularly if the drinking water is to be derived from wells. With regard to the former it may prove necessary to make several soundings, but there is no doubt whatever that water can be found in the neighbourhood of Tebuk by sinking wells in suitable spots in quantity sufficient for almost any number of pilgrims.

The quality of the water derived respectively from the spring near the *kala'at* and from the large well at the station was found to be very different, as shown by the following analysis. The spring water was clear; had no odour; contained 14·1 parts of chlorine as chlorides, 0·074 part of nitrogen, of which 0·063 occurred as nitrates, 0·003 as free ammonia, and 0·007 as organic nitrogen; it consumed 0·0204 part of oxygen in the permanganate process during three hours at 27° C.; its total hardness was 25·42 and its permanent hardness after boiling 15·32; finally, the "total solids" were 47·8. All the preceding figures represent parts per 100,000. The water from the station well, on the other hand, gave the following results. Its appearance was clear; it had no odour; it contained 36·7 parts of chlorine as chlorides, 0·333 of nitrogen, of which 0·328 occurred as nitrates, 0·002 as free ammonia, and 0·003 as organic nitrogen; it consumed 0·0481 part of oxygen in the permanganate process during three hours at 27° C.; its total hardness was 27·98 and its permanent hardness 18·02; and finally its total solids were 153·5. It will be seen that the well water was inferior in every respect to the spring water. It would be possible to employ the spring water for the lazaret, but it would be in every way preferable that this institution should have its own wells, entirely independent of the village. It will, however, be necessary to make multiple analyses of the waters found in the new soundings to be made near the lazaret site. Should these analyses give results as unsatisfactory as the single analysis of the station well just quoted, then it will become necessary to find means for improving the water-supply. Perhaps the best solution will be the putting up of a large distilling apparatus in which the well water would be distilled before distribution to the pilgrims, as is done in the lazarets of Camaran and Abu-Saad (Jeddah) in the Red Sea. The cost would no doubt be considerable, but it seems probable that this additional outlay would be compensated to some extent by economy effected in the length of drain pipes. For this reason: if the underground water is going to be distilled before being drunk there will not be the same necessity to carry the sewage matter far away to the west of the "cordons," as referred to above. The system of "fosses à fond perdu" will in all probability be adopted and (if a distilling apparatus is put up) it will be sufficient to have these fosses some 20 metres away from the barrier round each cordon, whereas if undistilled water were to be provided to the pilgrims it would be necessary to prolong the drains to such "fosses" at a distance of perhaps some hundreds of metres to the west of the cordons. In any event, the question of the water-supply for the Tebuk lazaret still requires some careful consideration and further observations before it can be regarded as satisfactorily solved.

While on the subject of wells, I should like to call attention to the following. Up to the present neither at Ma'an nor at Tebuk has the water derived from wells sunk in the desert shown any tendency to deteriorate or to become salter with time. But at Hedieh, a place situated between Medaini-Salih and Medina, this has been observed; a well gives fairly potable water for a few days, then it gradually gets more and more brackish, and in perhaps a fortnight's time is so salt as to be undrinkable. It may be recalled that precisely the same phenomenon was observed in the wells sunk in the desert outside Jeddah. In THE LANCET of July 6th, 1907 (p. 51), was published a reprint of a photograph showing the curious honeycombed aspect of the country near Jeddah, resulting from the sinking of innumerable wells. Those wells were sunk quite close to one another and in succession (though at what intervals of time I do not know), yet each is said to have presented the same series of phenomena. What is the explanation? I have been in correspondence with Meissner Pasha on the subject and this highly experienced engineer is equally puzzled. He suggests that at Jeddah the explanation may be that the well is a deep one, passing through an impermeable stratum, and that too active pumping may have led to infiltration of sea-water to re-establish the equilibrium in the undergound water. But no pumps existed at these desert wells near Jeddah, and the explanation is not applicable to wells far from the sea, as in the case of those on the Hedjaz railway. Can it be due to evaporation? This can scarcely be the solution, as these wells are often very deep and the surface of water relatively small. Is the phenomenon due to the action of some unknown micro-organism, producing conditions under which the water, when exposed to the air, becomes capable of dissolving more salts than when not so exposed? Perhaps some of the readers of THE LANCET may be able to furnish the explanation of a phenomenon which is of very practical importance when water has to be provided to large numbers of persons in regions where these conditions prevail. The Commission did not visit Hedieh, where, as stated above, this difficulty with the wells has been met with. A sample of the water from there was, however, procured and the analysis gave the following results. It had a yellow colour and an earthy smell; it contained no less than 142 parts of chlorine as chlorides; the nitrates were not estimated, but there were 0·013 part of nitrogen as free ammonia and 0·010 as organic nitrogen; the oxygen consumed in the permanganate process during three hours at 27° C. was 0·6376; the degree of total hardness was 70·3 and of permanent hardness 43·36; the total solids were 396. This water was clearly utterly unpotable; it was the worst of all the waters examined. To this, no doubt, may be ascribed the fact that during last winter's cholera epidemic Hedieh suffered more than any other place to the north of Medina.

To return to Tebuk, the village here contains only about a couple of hundred inhabitants. They are of a mixed race, largely Abyssinian, and many are little, if at all, removed from pure negroes. There is no *kaimakam*, and the only representative of Turkish authority is the *mudir* of the village. We here met Sheikh Harb, the well-known head of the Beni Attiyeh tribe. This tribe is said to number some thirty thousand men and people an extensive region, of which Tebuk glass valve, with no indiarubber attachment, "which requires very little regulating, cannot leak, become clogged, drop out, or be pulled out by the infant, and which yet allows an even supply of air behind the column of milk." The valve is formed by a hole in the neck of the bottle and a longitudinal niche cut in the neck of the stopper, which is kept from dropping out by an easily removed metal collar. When the niche and hole are in register the valve is opened on the principle of a drop bottle, except that the valve gives ingress to air instead of egress to fluid. We find that by turning the valve partly out of register the flow from the teat can be evenly regulated, and we consider that the bottle has the advantages which we have stated and regard it as a useful hygienic appliance for the nursery. The teat is non-collapsible and can be boiled without injury. Messrs. Kirby and Co. ask us to state that a sample bottle will be sent free to any medical man on application.

DYSPEPSIA: A NEW TREATMENT.

THE following postcard was addressed recently to a physician in charge of out-patients at a London general hospital:—

> SIR,—I have read rightly or wrongly that typhoid fever is a specific for dyspepsia, a thing I am a martyr to. I have spent no end of money trying to get cured, visiting about 50 doctors without result, also have attended St. ——'s nine months. Now I am only 23 and ambitious. I am willing to do anything to get rid of my malady and if it is possible to be inoculated with the fever I am willing to make the experiment.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Herbert F. Waterhouse, W. G. Spencer): at 5.30 P.M.

Paper:

Mr. James Berry and Mr. Paul L. Giuseppi: Traumatic Rupture of the Intestine, with a Case of Recovery after Operation and an Analysis of the 125 Cases which have occurred in 10 London Hospitals during the last 15 years.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—Arthur Whitfield, E. G. Graham Little): at 5 P.M.

Cases:

Dr. Dawson: (1) Sclerodermia Diffusa; (2) Acne Agminata.
Dr. Pernet: Granuloma Annulare (Female).
(And other Cases not yet notified.)

FRIDAY.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretary—Reginald Morton): at 8.30 P.M.

Paper:

Mr. W. Deane Butcher: The Amsterdam Congress of Electrology and Radiology.
(Lantern slides and radiograms will be shown).

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

NOTICE.—A Discussion on the Influence of Heredity on Disease, with special reference to Cancer, Tuberculosis, and Diseases of the Nervous System will be held at a SPECIAL MEETING OF FELLOWS OF THE SOCIETY on Wednesday, Nov. 11th. Fellows who desire to take part in the Discussion are invited to send in their names to the Secretary.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Annual Meeting. 8.30 P.M., Ordinary Meeting. Mr. C. B. Lockwood (the new President): Address. Mr. J. R. Morison (Newcastle-on-Tyne): Notes on a Case in which a Portion of a Lung was excised.

SOCIETY FOR THE STUDY OF INEBRIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—4 P.M., Discussion on the Relation of Alcohol to Feeble-mindedness (opened by Dr. W. A. Potts).

HUNTERIAN SOCIETY, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Dr. J. Mackenzie: The Bearing of Hunter's Work on Recent Advances in the Study of Heart Affections.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Major R. J. Blackham, R.A.M.C., D.P.H.: The Micro-organisms of Dysentery.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Cases by Mr. M. Ramsay, Mr. S. Stephenson, Mr. A. Ogilvy, and others. 8.30 P.M., Mr. F. G. Thomas and Mr. J. H. Parsons: A Case of Dipterous Larva in the Anterior Chamber.—Mr. N. B. Harman: Six Generations of Piebalds. (Opening Meeting of the Session.)

CHILD STUDY SOCIETY LONDON, Parkes Museum, Margaret-street, W.

THURSDAY.—8 P.M., Dr. C. W. Kimmins: Introductory Address on the Relation of the Curriculum to the Development of the Child.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 20, Hanover-square, W.

FRIDAY.—8.30 P.M., Dr. A. E. Horn: An Investigation of Cerebro-Spinal Meningitis in the Northern Territories of the Gold Coast (with microscopic demonstration).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fieds, W.C.

FRIDAY.—5 P.M., Prof. Keith: On Specimens illustrating Malformations of the Rectum and Anus. (Museum Demonstration)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. J. McCann: How to Diagnose Cancer of the Womb (with lantern slides).

TUESDAY.—4 P.M., Dr. H. Mackenzie: Clinique (Medical) 5.15 P.M., Lecture:—Dr. G. H. Savage: Borderlands between Badness and Madness.

WEDNESDAY.—4 P.M., Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M., Lecture: Mr. C. R. B. Keetley: Affections of the Toes, Feet, and Ankles.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Grant: Remarks on Prurient Nasal Discharges.

FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 4.30 P.M., Lecture:—Sir R. D. Powell, Bart., K.C.V.O.: Opening Address.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of th[illegible] Lecture:—Dr. Pritchar[illegible] and Surgical Clinics. X[illegible] 2.30 P.M., Operations. 5 [illegible]

THURSDAY.—10 A.M., Mr. [illegible] Selected Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Treatment of Typhoid Fever.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eyes. 2.30 P.M., Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Mr. Lawrence: Nasal Obstruction.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Prof. Hewlett: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. Carless.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Non-valvular Diseases of the Heart.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. J. H. [illegible] tient (Dr. Whipham); Nose, [illegible] Rays. 4.30 P.M., Medical [illegible]

TUE[illegible] Out-patient (Dr. Auld). [illegible] Carson). Clinics:—Surgical [illegible] Giles). 4.30 P.M., Special [illegible]ases (Dr. Chappel).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. Giles). Clinics:—Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X Rays. 3 P.M., Medical In-patient (Dr. Chappel). 4.30 P.M., Lecture:—Mr. W. Edmunds: The Treatment of Tuberculous Glands.

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Surgical Operations (Mr. Edmunds). Clinics:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks).

treatment under proper conditions. The coöperation of the hospitals and the General Dispensary being gained it was still necessary that the aid of the general members of the medical profession should be secured and if this was obtained the scheme offered great hopes of success. After Mr. Chamberlain's exposition was concluded the scheme was discussed and though a certain amount of opposition was apparent a motion deprecating the revival of any suggestion for the establishment of a public medical service was lost by a large majority, and Mr. M. Hallwright, Dr. J. A. H. White, Mr. J. Neal, Dr. G. Bryce, Mr. J. W. Ensor, Dr. H. W. Pooler, and Mr. F. A. L. Burges were appointed to act upon the committee which is dealing with the new scheme.

The Encouragement of Personal Cleanliness.

The city council seems to have faith in the old saying that cleanliness is next to godliness and with the object of encouraging an agreeable virtue it has decided to establish a number of cottage bathing establishments where a bath may be obtained for the sum of 1*d.* and a piece of soap for ½*d.* The first establishment was opened on Oct. 1st in Digbeth where cleanliness is not usually too obviously intrusive. The experiment will be watched with interest and if the establishments succeed and pay their way perhaps no one will have any cause to complain except the heads of families who may have been induced to squander on a single bath a sum of money which, had it been judiciously expended on coal and soap, would have served not only to provide hot water and lather for the whole family but also heat for cooking purposes and warmth for the house. Apparently the city fathers think much water better than a little thrift.

The Birmingham District Nursing Society.

The new home of our District Nursing Society in Summer Hill-road was opened on Oct. 2nd by Mrs. William Kenrick. It is thoroughly up-to-date in arrangement and equipment and will provide accommodation for a superintendent, an assistant superintendent, and 16 nurses. The building has cost £5000. To meet this the committee has provided £2,500, and it appeals to the public for the remaining half and also for additional subscriptions of £450 per annum to maintain the present staff and to provide extra nurses for the Saltley district, where they are urgently needed. The furnishing of the new house and the laying out of the garden have been more than provided for by the generosity of the Right Hon. William Kenrick and Mrs. Kenrick, who have initiated, stimulated, and helped so many useful projects in Birmingham.

Medical Appointments at Bilston.

Some three months ago Dr. T. R. Bailey, the medical officer of health to the Bilston council, received three months' notice to terminate his appointment at the infectious hospital, on the ground that all the medical appointments in the control of the council should not be in the hands of one man. At a meeting of the council on Sept. 23rd the clerk reported that in accordance with his instructions he had advertised the appointment but no applications had been received, and after some discussion an unfortunate incident was terminated by the reappointment of Dr. Bailey.

The Birmingham Hospital Sunday Fund.

At a recent meeting of the general committee of the Hospital Sunday Fund a subcommittee reported that it had considered applications from the Jaffray Hospital, the Hospital for Skin and Urinary Diseases, the Midland Counties Asylum for Feeble-minded Children, and the Crippled Children's Union. The decision arrived at with regard to the various claims was that they could not be acceded to unless other charities with equal claims were similarly treated, and it was resolved that the usual appeal should be made to the clergy and ministers of the city on behalf of a collection to be made on Oct. 25th next and that the proceeds of the collection should be distributed in the same proportion as last year.

Medical Inspection at King's Norton.

At a recent meeting of the King's Norton education committee Dr. Jones reported that the inspection of 1946 children had revealed that 69 per cent. had defective teeth, 25·7 per cent. had enlarged tonsils and adenoids, about 18 per cent. had dirty heads, 4·4 per cent. had spinal curvature, 3·6 per cent. had heart disease, 2·3 per cent. had lung disease, 1·5 per cent. had bad ears, and of 735 cases tested 7·2 per cent. had defective vision. The school hygienic subcommittee recommended the appointment of a school nurse at a salary not exceeding £50, to assist the school medical officer, and although the council had previously refused to make such an appointment the obvious necessity caused an alteration of opinion and the appointment was sanctioned.

Oct. 6th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Farewell Dinner to Mr. George Gibson Hamilton, F.R.C.S. Eng.

A FAREWELL dinner was given to Mr. George G. Hamilton, late honorary surgeon to the Royal Infirmary, at the Adelphi Hotel on Oct. 2nd, by friends and colleagues, on the occasion of his leaving Liverpool to reside in Boscombe, Bournemouth. For the past 25 years Mr. Hamilton had been engaged in surgical practice in Liverpool. His first appointment was at the Children's Infirmary, thence he passed on to the David Lewis Northern Hospital as honorary surgeon, whilst for the last 15 years he had been on the staff of the Royal Infirmary, in the first instance as assistant surgeon, and afterwards succeeding the late Sir William Mitchell Banks as honorary surgeon in 1902. The Lord Mayor (Dr. Richard Caton) presided and in felicitous terms spoke of the good work accomplished by Mr. Hamilton in Liverpool, and of the loss that the city, the Royal Infirmary, and the medical school will sustain through his departure. In reply to the toast of his health, proposed by Dr. E. W. Hope and supported by Mr. Charles Lancaster, Mr. Hamilton said he felt flattered that so many colleagues and friends were with him that night, notably the Lord Mayor who with all his numerous engagements had found time to be present. He also remembered that Dr. Hope, now the esteemed medical officer of health, had been a house surgeon with himself, somewhat over a quarter of a century ago. In those days house surgeons were appointed to the Liverpool hospitals from all parts of the country. He hoped to see soon arrangements made by which house surgeons should be regularly interchanged between the large teaching hospitals as had been the custom in Germany for a considerable time. Mr. Edgar A. Browne then proposed the health of Mrs. George Hamilton in a charming and humorous speech. Mrs. Hamilton and a few other ladies were present to hear the speeches. Covers were laid for about 60 gentlemen.

Liverpool Royal Infirmary.

At a meeting of the election committee of the Royal Infirmary held on Sept. 30th Mr. F. A. G. Jeans was appointed honorary assistant surgeon in succession to Mr. William Thelwall Thomas, promoted honorary surgeon on August 10th.

Cost of the Civic Hospitals for Infectious Diseases.

In the recent report of the medical officer of health on the Liverpool city hospital accommodation it is shown that over 40 per cent. of the total accommodation is provided in buildings of a temporary nature, and as recent experience has proved that the present accommodation is only barely sufficient for actual requirements it is of the greatest importance that the existing buildings, whether of a permanent or temporary character, should be *maintained in* a thoroughly satisfactory condition, otherwise the situation might become serious at any time. The cost of maintenance of the city hospitals for 1907 was: north hospital, £9224; south, £5570; east, £8250; Parkhill, £12,183; Fazakerley, £11,244; and Fazakerley annexe, £4080; making a grand total of £50,556.

Oct. 6th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Presentation of Portraits of Sir T. Clifford Allbutt and Mr. T. Pridgin Teale to the General Infirmary.

SOME time ago it was decided by the numerous friends of Sir Clifford Allbutt and Mr. Teale that they should be requested to sit for their portraits in order that there should be preserved in the city with which they had been so long

Communications, Letters, &c., have been received from—

yet decided as to whether such patients should be taken into the hospital or not. It was agreed to recommend to the town council that the remaining portion of the work should be proceeded with at once at the estimated approximate cost of £10,400.

Oct. 3rd.

IRELAND.

(From our own Correspondent.)

Personal Cleanliness of Dairy Boys.

An item of discussion which will, I trust, prove productive of good and palatable fruit in the near future has been again before the South Dublin district council. At a previous meeting some critical remarks had fallen from various members regarding the personal cosmetics and sanitation of city dairy boys, the publication of which elicited a resolution from the Dublin Cowkeepers' and Dairymen's Association that was communicated to the last meeting of the council by the secretary. It was as follows: "With reference to the statements of the rural district council of South Dublin, relative to the city dairy boys, we, who are employers of a large number of dairy boys in the city, hereby protest against the statements made as untrue and undeserved and in no way warranted, and we desire to point out that the boys are under the strict and constant supervision of officers of the public health department of the corporation." The opinions expressed by members during the discussion presented some divergence, though hardly so much as usual. Alderman Flanagan said that, notwithstanding the "resolution," "some of the dairy boys were not as clean or as tidy in their dress and persons as they ought to be." Mr. Landy said that "some of the dairy boys were exceptionally dirty. The council *only* objected to the dirty ones." And Mr. Curtis stated that he had been "subjected to abuse and insult from dairymen and boys for having dared to mention the matter at the council." The communication was marked "read." Most readers will probably agree, I believe, that the state of things referred to—and revealed in the speech last quoted—called for some critical scrutiny. And very many consumers of Dublin milk continue to hope and pray that the discussion may be repeated, even to the manifest production of very visible results!

Children's Hospital, Dublin.

What is known as "Pound day" was held recently in aid of St. Mary's Convalescent Home, Cappagh, Finglas, in connexion with the Children's Hospital, Temple-street, Dublin. The charitable having been previously requested to help by presenting a "*pound* of something" that may help to provide for the little patients, those who find the donation of a £1 note beyond their means can send a pound of tea, sugar, rice, biscuits, flour, fruit, soap, starch, candles, matches, or other useful commodity. Children's clothes, furniture, articles for the table, household utensils, &c., are also welcome. All donations are delivered from the principal shops free to the hospital. It was announced at a meeting of the committee that a letter containing 12 stamps had been received from a boy patient who had recently left the hospital after circumcision. Coming from a child it was greatly appreciated. Among the presents was a case of soap from the manager of a city laundry.

Boards of Guardians v. Dispensary Medical Officers.

It is a melancholy fact that the septuagenarian practitioner, Mr. S. McDermott, to the case of whose pension I recently referred in this column as a specimen of the gratitude of boards and councils, died before he had an opportunity of drawing the first instalment of the superannuation allowance which had been accorded to him by the Local Government Board, in spite of the determined opposition of the guardians of the union, to the poor of which he had devoted the best energies of his life during a whole generation. And another case of the characteristic generosity of our Irish boards of guardians has just been reported from Tralee: a motion to rescind the grant of his superannuation allowance to Mr. J. Hanlin was lost by but one vote—at a board meeting which included over 50 members. Still another specimen of the same type of feeling and conduct is reported from the Ballyshannon Union, where Mr. G. R. Corscadden has been medical officer (Ballintra Dispensary District) for nearly 30 years. Having been obliged to give up his residence and not being able to secure one in a convenient part of his district, he suggested the building of one to the guardians, which owing to cheapness of labour and material would not cost more than £500. He received a curt refusal and was told that he might take lodgings at Rossnowlagh, which is situated at a distance of eight miles from the centre of his district, and that such accommodation would serve well enough for his time! Verily, the life of the Irish dispensary medical officer is not a happy one.

Longevity in Donegal.

As might be expected from its very numerous contributions to the annals of longevity, the county of Donegal has taken up a conspicuous position in the relative number of its inhabitants who have presented claims under the Old Age Pensions Act. On Sept. 29th it was announced in the *Freeman's Journal* that 1200 forms of application had already been obtained from the Donegal head office and sub-offices. Some of these had possessed the legal age qualification more than 30 years ago. Charles Kelly of Burbane, in the parish of Inver, bases his claim on an age of 111 years; John McGinty, of the parish of Donegal, gives his age at 106; and Bryan O'Donnell of Tower, parish of Inver, at 103. Of the last-mentioned claimant it has been stated that he has always used the Irish language only, having never uttered a sentence of English during the whole of his long life! All three of the venerable applicants are described as being in good health, both physically and mentally.

Outbreak of Enteric Fever at Clontarf.

The suburban township of Clontarf has recently been visited by a rather widely spread epidemic of enteric fever. In the houses of one "road" no less than 34 cases have been reported. A large proportion of the patients are children and it is stated that the first case occurred in a school. The sanitary authorities are taking all possible precautions to prevent the spread of the fever. Sir Charles Cameron has written to the papers warning the residents in Clontarf to use disinfectants in the drains and to boil all milk before using; and this procedure was supplemented by warnings to the pupils in the various schools of the district to tell their parents of Sir Charles Cameron's advice. The outbreak appears to be so far confined to Clontarf; and the great majority of the cases have occurred in the roads running inland from the sea-shore. Of the explanations hitherto attempted, one is that the infection arose from the "sloblands," a sector of the indenting strand which has been cut off by the railway and is being gradually filled up to land level by the dumping of refuse. Another is that the making of new sewers has thrown up long buried soil of unwholesome properties; while yet another is the suggestion that the use of milk kept under cover during the unwonted temperature of the current heat-wave has led to the genesis of the mischief. In this connexion the following letter has appeared in the *Freeman's Journal* of Oct. 2nd:—

Public Health Committee, Municipal Buildings,
Dublin, 3rd October, 1903.

Sir,—I have received letters and visits of several persons relative to the sloblands at Fairview, now being filled in by street sweepings, &c. The epidemic of typhoid fever at Clontarf is attributed to emanations from these sloblands. May I state that none of the recent cases of typhoid fever have occurred amongst the people residing near the sloblands.—I am, Sir, your obedient servant,

Charles A. Cameron, Medical Officer of Health.

The Belfast Abattoir.

The Belfast Corporation on Oct. 1st, at its monthly meeting, decided to authorise the erection of a new abattoir on the Stewart-street site at an estimated cost of £32,118, in accordance with plans passed by the city surveyor. There was a long and animated discussion and frequent amendments were suggested, but in the end the motion was carried by 31 votes to 12.

The Belfast Natural History and Philosophical Society.

Sir John Byers was on Oct. 2nd unanimously elected President of the Belfast Natural History and Philosophical Society for the session 1903-04.

The late Mr. David Wilson, L.R.C.P. Edin., M.R.C.S. Eng.

Deep regret will be felt by a numerous circle of friends and patients at the announcement of the death (after a lingering illness due to a paralytic seizure) of Mr. David Wilson who for many years practised in Whiteabbey, written by Charles Darwin and Alfred Wallace "On the Tendency of Species to Form Varieties, and on the Perpetuation of Varieties and Species by Natural Means of Selection," which constituted the inception of that theory of evolution which has since dominated scientific thought and which has for its basis the facts of inheritance. But granting the importance of the subject, what has it to do with Harvey? Not much perhaps, if we limit our thoughts to his great and enduring work on the circulation of the blood. But we know that other problems in physiology occupied his mind. It is true that it was late in Harvey's life, when his friend Dr. Ent obtained from him for publication his book "De Generatione Animalium," and almost against his will, for he knew that it was incomplete. Yet it seems that he had been patiently collecting facts for it many years before and one whole section of it, on the generation of insects, had been destroyed by his political enemies as ruthlessly as they might have wrecked a cathedral. One is tempted looking on his two great works to contrast them by saying that the "De Motu Cordis et Sanguinis" arose complete, conclusive, victorious, like Pallas from the head of Jove, while in the "De Generatione" we witness his painful and laborious searchings after truth. But that would be a superficial contrast, for we know that the truth concerning the circulation was incubating in his mind for some ten years before it found final expression, and we have been taught by the Harveian orator of two years ago that the growth of truth is slow. Granted that in the "De Generatione" he did not attain to the full knowledge which he desired (that indeed was impossible with the meagre means of observation at his command), yet we cannot but admire his method in the collection and presentation of facts within his reach. I imagine that no better account of the phenomena of development could have been given at that date than Harvey gives in his chapters "On the Inspection of the Egg" and "Of the Order of the Parts in Generation as it appears from Observation." It is only when facts fail him that we fail to follow his conclusions. To give an example. "It is certain," he says, "that no semen reaches the uterus"—he had no microscope wherewith to identify the spermatozoa—"therefore the woman becomes fecundated without the coöperation of any corporeal agent, in the same way as iron touched by the magnet is endowed with its powers and can attract other iron to itself." A bold analogy indeed, drawn from a branch of science which then was very young; but it shows, like many other passages from his works, that Harvey, with all his zeal and reverence for facts, had his gaze fixed on the great mysteries of life, on the marvel of conception, on the efficient cause (to use his own phrase) of reproduction, and on heredity in its widest sense. For does he not himself say, "In truth there is no proposition more magnificent or more useful to ascertain than this: How are all things formed by an univocal agent? How does like ever generate the like? And this not only in productions of art (for so house builds house, face designs face, and image forms image), but also in things relating to the mind; for mind begets mind, opinion is the source of opinion. Democritus with his atoms, and Eudoxus with his chief good, which he placed in pleasure, impregnated Epicurus; the four elements of Empedocles, Aristotle; the doctrine of the ancient Thebans, Pythagoras and Plato; geometry, Euclid. By this same law the son is born like his parents, and virtues which ennoble and vices which degrade a race are sometimes passed on to descendants through a long series of years. Some diseases propagate their kind, as lepra, gout, syphilis. and others. But why do I speak of disease when the moles, warts, and cicatrices of the progenitor are sometimes repeated in the descendant after many generations? Every fourth birth, says Pliny, the mark of the origin of the Dacian family is repeated on the arm. Why may not the thoughts, opinions, and manners now prevalent return again, after an intermediate period of neglect? For the divine mind of the eternal Creator, which is impressed on all things, creates the image of itself in human conceptions." I quote these words of the great master in the hope of persuading you that some remarks on heredity may not, after all, be alien to a Harveian oration; and if I invite your attention to that subject for the brief time that remains, it is not, believe me, with any vainglorious expectation that I shall add to your knowledge either of facts or of theory, but only that I may perchance—again to quote the words of Harvey—"stir up the intellects of the studious to search more deeply into so obscure a subject."

It would be interesting, doubtless, to consider what answers modern authors make to the question over which Harvey puzzled—namely, how comes it that the embryo is laid down, with definite parts, in a definite order, and so that it eventually resembles its parent? That would mean a consideration of such theories as the pangenesis of Charles Darwin, the determinants of Weismann, and the "mneme" or unconscious memory of Richard Semon, a doctrine set forth, you will remember, by Francis Darwin in his presidential address to the British Association this year. But these things I am not competent to expound, neither would time permit me to try. I will therefore only raise such points as seem to have direct practical bearings for us.

And first comes the old question, "Are acquired characters transmissible?" Have those external forces and events which help to fashion our own life and being any similar effect, through ourselves, upon our unborn children? I think that the plain unlearned man would certainly say "Yes," and so did the learned till a short time ago. Lamarck's views of natural history and the theory of natural selection as first propounded by Darwin assumed the possibility of such transmission, and numerous illustrations of it as regards man and his diseases were collected, perhaps in an uncritical fashion, by Prosper Lucas and others. But it is incompatible with Weismann's theory of heredity which is now so widely held. The central idea of that theory is the "continuity of the germ plasm." By germ plasm is meant the formative tissue out of which, or under the guidance of which, each individual is fashioned. It matters little to the theory whether this germinal plasm is identified with the germinal cells (as formerly) or with the much minuter particles of their nuclei known as "chromosomes." The germ plasm is continuous—that is to say, it is not manufactured afresh within the individuals of each generation for the purpose of procreating the next, but it is handed on from generation to generation, *only* changing in this sense, that as each successive *individual* is made, a portion of the germ plasm is set aside within him whereby he will carry on the work of generation when his elders have perished. So that we are not links in a chain of life but rather flowers or leaves which spring from a common stem, the germ plasm. And in the same way I am not, strictly speaking, my son's father, but his elder brother (to be accurate I should say his half-brother), nor am I my father's son but his younger brother; the real father of us all is the family germ plasm, and my duty to that father is to accommodate him in the house he has built, my body, till he has built himself a new one, my son's body. The reason for the resemblance of successive generations to each other is now obvious: it is because they are all brothers, made out of the same stuff on the designs of the same architect. It is obvious, too, that the effects of external conditions on one generation will not be reproduced in another unless the same external conditions happen to act again. If a caterpillar has gnawed a hole in a leaf upon a tree the other leaves will not have holes in them unless the caterpillar have gnawed them too.

Then do the ills acquired by the parents have no effect on the well-being of their children? Few people, surely, would maintain that. For the germinal plasm is lodged, at any rate, in the parent's body; if he dies, it dies; and if he suffers from any deeply reaching disorder of nutrition the probability is that it must suffer too. And such nutritional possibilities, I need hardly say, are numerous. We need not suppose, then, that exhausting diseases which may affect the whole organism—such as alcoholism, diabetes, syphilis, or phthisis—are without effect upon the health of our children. And is it not also possible that similar far-reaching effects may be produced by other influences not strictly nutritional, say, for example, some nervous shock? May not a violent commotion of the branches of the tree affect its stem?

Still, it is one question whether disease acquired by a parent can produce ill effects on his children of a general kind (a thesis which, to my mind, can hardly be denied); it is another question whether, when a parent has acquired a particular disease, disease of the same or of a similar kind is likely to occur in his children. Those who deny this absolutely say, first, that it never happens. Observation must be the test of that. Secondly, that it cannot happen,

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Welcome and Unwelcome Invaders.

SILY alarmed at the advance of Asiatic cholera Italy is g every precaution to keep it at bay, and what with enic surveillance at the frontier and the seaports, supple- ted by the enforcement of sanitary measures within her household, she is sparing no effort to ward off the fell der and to minimise what has hitherto been its most tive auxiliary—domestic panic. As to the first of these es *of defence*," which may be summed up in the d "quarantine," she is in no danger of lapsing into issness; nay, the contrary is the fact, insomuch that she pt to repeat her mistaken policy of previous visitations in her anxiety to exclude the coming foe, cholera, to e away the coming friend, the English-speaking visitor.

"Incidit in Scyllam cupiens vitare Charybdim";

by vexatious conditions imposed on "arrivals" by rail- train or steamship, she often, quite needlessly, shuts out element, never unwelcome, the free-handed "stranger hin her gates." As if indeed to correct the disposition in ch the excessive zeal and harassing regulations at tier or seaport originate, she is laudably employed in suring an all too emotional and ecstatic public as to the nature of cholera and the best means of antagonising it; so we are witnessing the opportune "Conferenza" and well-timed popular lecture at which the voice of the pro- sion is heard to salutary and inspiriting effect. In Rome other day the medical authority of Dr. Santoliquido—a mber of Parliament who is also officially responsible for "Direzione Generale della Sanità Pubblica"—intervened an assembly of health officers and railway functionaries set before them the best means of preventing the pagation of the disease while sparing the travelling rld every avoidable inconvenience; and to mention provincial school out of many others—at Siena, Dr. lavo, of the University, gave wise counsel to the general blic, first as to the nature of the disease, and next as to readiest *means of diagnosing it, isolating it, and treating* . As to the railway service, there will be started a train pecially for the "*emigrants*" employed in labour abroad o are returning to their homes, a train which, besides ving intercommunicating carriages, will have also a wagon which there will be a completely equipped "stazione di sinfezione," with another wagon attached to it conveying e "personale sanitario," the "armadio farmaceutico," and "sezione d'isolamento." The institution of these trains— be started the moment the hygienic outlook seems to arrant it—is a new departure for Italy; and it will have justification in contributing to exorcise that "spirit of nic" which has hitherto been so disastrous—notably in e terrible "explosion" of cholera just 24 years ago in aples, where more died from sheer fright than from the tual disease. The institution may be taken as a typical ample of the more scientifically inspired policy which imates Italy under the threat of plague, of cholera, or of her pestiferous visitants, reassuring her own public, while lieving the incoming stranger of the vexatious ordeal itherto imposed on him at every arrival platform or landing ay.

Disease-conveying Banknotes.

Once and again the warning has sped throughout Italy as the danger incurred by the handling of her "paper urrency"—that is, of banknotes representing in value 0 francs or even 5 francs respectively. Things are not so ad in this respect as when "biglietti di banca" for 2 francs, franc, and (*horresco referens!*) half a franc (5*d.*) were in ree circulation, and when, especially in the case of the ast named, the viscous dirt with which it was coated ame to be recognised and dreaded as a potent vehicle f infective disease. Copper, nickel, and silver are ow in use for sums below 5 francs (4*s.* 2*d.*); but still he 5-franc note is in universal currency and sometimes so lthy that the public, now awakened to the "septic touch," s increasingly reluctant to handle it. The 10-franc note is erhaps a shade less tainted with the sordes accumulated in ransmission, but still it is accepted with misgiving by all ut the ignorant or those whose necessity countervails con- iderations of health. The English-speaking traveller in Italy is now demanding with growing insistence from bankers and money-changers the metallic equivalents for these risky "*assignats*," and Italians are seconding him in his preference till, it is to be hoped, the Treasury will see its way to replacing its "carta-moneta" by the silver and the gold of a former, if not a better, day.

The Crusade against Malaria.

The Italian Prime Minister, His Excellency Signor Giolitti, has nominated a "commissione technica" to examine and to discuss the numerous data collected by the Minister of the Interior in the "Crusade against Malaria," after the enforcement of the laws enacted to antagonise the causes of the disease and particularly after the sale of State-provided quinine. The president of the commission will be the senator Dr. Guido Baccelli (who presides over the "Consiglio Superiore di Sanità"), assisted by Dr. Rocco Santoliquido, Professor Arnaldo Maggiora, Professor Alfonso di Vestea, and Professor Pietro Canalis. The secretary to the commission, an exceptionally strong one as will be seen, is the "medico provinciale," Dr. Mercanti.

Oct. 3rd.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Infant Mortality in Hungary.

THE vital statistics for last year show that although the general mortality has notably decreased that of infants has been hardly affected. It would seem that all the hygienic advances which have been made during past years, and which have proved so beneficial to the population at large, have hardly touched the fringe of infant mortality. Its magnitude depends upon alimentary disturbances, diarrhœa, too frequent feeding, and feeding with infected milk, &c. Experiments were made in Budapest with cow's milk from different suburbs, and it was found that dirt was invariably present, varying in amount from 1 to 72 milligrammes per litre. The first milkings always contain the most dirt, the amount of which decreases proportionally as the milking proceeds. From a hygienic standpoint it would be wise to discard the first milkings.

Operation for Mastoid Disease.

At the last meeting of the Budapest Royal Society of Physicians and Surgeons Dr. Fleischmann discussed the question of when to operate on the mastoid bone. He said that a review of the literature on this subject teaches us that suppuration of the middle ear, whether acute or chronic, involves danger to life. Further, that properly timed surgical intervention prevents the extension of the disease into the cranial cavity. The gravity of the disease depends solely on its locality. If the suppuration affects the middle ear or the cranial cavity then serious danger arises. In such cases operation is almost inevitable. The operation itself is not a dangerous one. The mortality of simple opening of the mastoid process varies, according to recent authorities, between 1 and 4 per cent. The radical mastoid operation is generally attended by about 8 per cent. mortality. In his (Dr. Fleischmann's) cases 12 simple operations (opening into the mastoid) resulted in one death. A study of the course of an acute mastoiditis without any operative interference affords a good idea of the indications for operation. The chief of these are as follows: 1. Extension of the disease into the cranial cavity characterised by persistent one-sided headache or any cerebral symptoms. 2. If mastoiditis be present, characteristic signs of which are pain and tenderness, over three or four days, immediate operation is to be resorted to. 3. When the discharge of acute otitis with mastoid symptoms does not diminish at all in the course of about two weeks of appropriate treatment chronicity must be expected, even though the mastoid signs diminish. Hence an operation is advisable.

An Adjuvant to the Finsen Light Treatment.

Dr. Morvay reports some interesting experiments in connexion with eosin stains as an adjuvant to the Finsen light. He has found that the addition of a very small amount of erythrosin to the culture media of bacteria caused a very much greater sensitiveness on their part to the yellow and green rays which were otherwise ineffective. The action least three generations; therefore, the facts can rarely be the result of the physician's direct observation. Again, the numbers in human families are at best so small that a single vitiating instance may make a large error in the proportion of normals to abnormals, and it is difficult to know what to do with stillbirths, children who die young, or others of whose condition nothing may be known. This numerical difficulty may be partially met by adding up the totals of many families, but that is certainly a method to be employed with caution. And this, too, has to be remembered: that certain modifications have been introduced into the original Mendelian laws which are, no doubt, necessary and correct, but which tend to mask their simplicity of application. Such, for instance, is the interaction of two sets of characters, whereby the dominance of one member of an allelo-morphic pair over the other is rendered conditional on the presence of a third character. Thus it has been supposed, on the analogy of other facts, that hæmophilia is a character which becomes dominant or recessive according as the sex of the person is male or female and that this accounts for the rarity of female bleeders. Such modifications and complications may make the interpretation of a pedigree as difficult as its construction; and it may be necessary to refer it for its interpretation to someone who knows the business well.

In some diseases where family pedigrees are not easily obtainable all that we can say is that the facts agree with some side deduction from Mendel's theory. It appears that first cousin marriages form one of the causes of alkaptonuria, and it is pointed out that this is just what would happen if alkaptonuria were a rare recessive character in the Mendelian sense. The character being recessive would not appear on the surface until two similar hybrids—hybrids, that is, possessing the character—intermarried. And since the character is rare, two such hybrids are not likely to meet unless they are of the same family. And that is one thing that may be said, on Mendelian principles, about consanguineous marriages in general. They are a means of bringing to light hidden (recessive) characters. Such characters may be good or bad, we cannot tell beforehand. So that the State of Wyoming, which Lord Rosebery tells us has forbidden first cousin marriages, may have prevented evil or may have stifled good.

The study of heredity in disease is likely to be particularly interesting in the sphere of the nervous system. For in the first place heredity is here an agent of great power: it ranks with injuries, infections, and intoxications as one of the principal causes of chronic nervous degeneration. Again, in proportion as our civilisation becomes more and more elaborate, so we depend for progress more and more upon our nervous system, upon its flexibility and capacity for adjusting itself to the complication of our surroundings. This suggests the possibility that the ways in which heredity moulds this plastic material may be varied; that just as a young and growing community has to feel its way towards the establishment of its laws or its political system, so here perhaps those sequences which we call laws of heredity may not yet have attained a rigid uniformity. However this may be, there are at least two ways in which heredity manifests itself in diseases of the nervous system. The first relates to that common group of maladies known as neuroses. This group includes such affections as epilepsy, insanity, hysteria, neurasthenia, tics, alcoholism, &c., which are characterised, so far as we know them at present, by perverted nervous action rather than by coarse structural disease. They are related together in this way: that they seem to be the expressions, varied and interchangeable *inter se*, of some one underlying nervous defect; we may perhaps call them the ill-timed or inappropriate response of a nervous system which adapts itself badly to its surroundings. This deeply seated nervous defect, whatever its precise nature may be, is hereditary in a high degree, so that the "neuropathic family" is now notorious in medicine. One member of it may be epileptic, another insane, another eccentric, and so forth, but the faulty nervous constitution is the same in all. So much we know, but there is much more that we should like to know. How, asks Dr. G. H. Savage (in his presidential address to the Neurological Society) does this instability of nervous system originate? May it have begun through faulty nutrition of some ancestor so profound that his germinal tissues suffered with the rest of his body? That might suggest a hope that in time it might be rectified by reversing the process. Or may it be that his germinal tissues were old and effete when he undertook the process of procreation? Or is it, after all, some deeply ingrained fault originating we know not how and curable only by extinction of the stock or by repeated crossings with others that are more stable? We cannot answer certainly. Nor can we always tell what determines the special form of neurosis in the different individuals, why some should have epilepsy, some insanity, and so forth; nor why, as sometimes happens, some one of these morbid manifestations should repeat itself and not alternate with others. Melancholia, Dr. Savage tells us, is particularly apt to recur in several members of a family, and Dr. W. Aldren Turner says the same thing, I believe, of epilepsy. Nor yet do we know why some members of a neuropathic family should appear perfectly normal and some, perhaps, even better than their fellow-men. Here we think of the old saying that genius is allied to insanity. Mendelian writers sometimes tell us that we should learn the lesson of the blue Andalusian fowl. That farmyard sermon teaches us, *inter alia*, that from crossing two pure breeds which are considered undesirable a mongrel may result of a desirable character. May this happen with neurotic stocks? Can two such families atone for their existence by combining to produce a genius? One would hardly care to advise the experiment, and luckily our advice as to pairing is seldom asked and still less often acted on. The science of eugenics is still in its infancy; let us hope that when it becomes an active force physicians will have acquired such knowledge as will enable them to take their proper share in controlling it. Lastly, there is the important inquiry, what relation have these nervous manifestations, and the diathesis in which they have their root, to other diseases of more tangible nature, to gout, rheumatism, tuberculosis, the febrile state, &c. That there are such relations, and some rather close ones, this we know, but little more.

The second way in which heredity manifests itself as regards nervous disease is different. In this form a certain disease, definite in type, whose identity, as a rule, is easily recognised, appears in several members of a family, it may be in successive generations, it may be only in one generation. This class constitutes the group known as family diseases of the nervous system, which was discussed before the College last summer in a most interesting lecture by Professor Raymond. Such family disease is by no means limited to the nervous system, but in that sphere numerous and remarkable examples of it are to be found. Friedreich's ataxia is one of the best known examples. In this class of disease the precision with which the features of the particular complaint reproduce themselves is generally remarkable, and contrasts strongly with the shifting character of the neuroses which we have just considered. There are, I know, exceptions to this rule, which have been much insisted upon lately, either where the disease is incompletely developed in some individuals, or where different types may appear in different members of the same family; but still I think that, generally speaking, the reproduction is fairly accurate, so that the particular disease can be as easily recognised as can tabes dorsalis, disseminated sclerosis, or other non-family nervous disease. A general neuropathic taint need not necessarily exist in the family, though of course it may. The majority and the best known of these diseases present the clinical picture of a slowly progressive incurable paralysis, which may correspond anatomically to an exceedingly definite degeneration of certain nerve tracts. Thus Friedreich's disease affords us an exquisite example of combined system sclerosis beginning in the posterior columns, then affecting the pyramidal tracts, and involving in advanced cases the afferent tracts to the cerebellum as well. Hereditary spastic paraplegia has been shown by Strümpell to depend on a degeneration of the pyramidal tracts. Yet the patients are not born with these lesions, so that we cannot exactly call them malformations; they are born with a hereditary weakness of these nervous tracts, which break down under the stress of living. The age at which symptoms begin differs largely in the different diseases; the onset may be in early life, in early or late adolescence (instances of all these dates can be given in Friedreich's disease); in middle life or even later, as in Huntington's chorea or the spastic paraplegia just quoted from Strumpell. It is strange to think that a man can develop at that age a in, and adulteration of, food products. To this end the association appointed a committee to prepare a Bill founded upon the determinations of the Joint Standards Committee and which shall be formulated with a view towards uniform requirements throughout the several States. In the dual form of Government in this country laws adopted by the Federal Government can affect only articles of interstate commerce and therefore the real regulation of foodstuffs must eventually rest with the various States. The effort of the association to secure uniform and effective State legislation is on that account of the first importance and highly commendable.

Resignation of Dr. William P. Spratling, Superintendent of the Craig Colony for Epileptics.

The Craig Colony for Epileptics is about to suffer a severe loss by the retirement of its superintendent, Dr. William P. Spratling, who has accepted a position as professor of physiology in a medical college in Baltimore. Dr. Spratling has been the superintendent of the epileptic colony since its organisation and to him is due the credit of the success of this institution. He brought to its management a mind thoroughly equipped for the peculiar service which was required for success and a temperament adapted to meet patiently, but aggressively, the many obstacles which such a new and untried institution has to encounter in its early history. He has the satisfaction of seeing the colony finally established on a permanent basis.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Defective Eyesight amongst Parsis.

IN his special investigation into the condition of the eyesight of Parsi students and school children during the past year Dr. K. N. Karanjia, the honorary surgeon of the Ardisir Hormarji Wadia Parsi Ophthalmic Hospital, finds that defective vision is alarmingly prevalent among them. The most unobservant person in taking a walk in Bombay cannot but be struck by the number of young Parsis decorated with spectacles, but Dr. Karanjia says that these represent only a fraction of the defective sight which actually exists. The majority of those who need glasses, he says, cannot obtain them for want of money or go without through neglect, to the further injury of their eyes, resulting in pain and a handicap through life, and he appeals for funds to supply poor Parsis with spectacles free of charge. While this cause deserves a general response it is much more necessary to take steps to prevent the further injury of the eyes of the young. The Germans are a notoriously short-sighted people since they took to education owing chiefly to the illegible character of their language, and it is probable that the bad printing and small type used in Gujarati primers are also responsible for like troubles among the Parsis. More probably, however, the trouble is often caused by the learning of English from types insufficiently large a little later in school life. At whatever age the learning of a language is begun it should be prosecuted at first by means of the big type made for little children, for the strain on even an adult eye of reading unfamiliar characters is many times greater than that of reading characters of the same size which have grown familiar. Intelligently conducted ophthalmic tests should be made of the Gujarati characters, and if found injurious in their present form they should be modified, printed big, or abolished altogether.

Veterinary Work in the Central Provinces.

From the annual report on the veterinary department of the Central Provinces we learn that the conversion of the people in favour of the inoculation of their cattle against rinderpest has been in some places most striking. Pending the introduction of a new scheme in 1909 a small staff of veterinary assistants, paid from provincial funds, has been appointed. These have been generally employed on inoculation and to them are largely due a marked increase in the number of inoculations and the department's growing popularity with the people. Hitherto inadequate recruitment has been one of the main obstacles to advance, and the closing of the Ajmere Veterinary School and of the two years' class at the Bombay College has increased this difficulty. With the provincialisation of the department which the new scheme involves the scale of pay of veterinary assistants will also be raised, and it is hoped that the improvement in prospects will attract more candidates of a suitable class. Of course, the activities of the department are by no means confined to isolation work. Cattle-breeding farms have been established and bulls are distributed to stock-owners with the object of improving local breeds of cattle. This latter measure has not been so successful as anticipated and the question of altering the system is under consideration.

Central Provinces Medical Department.

The scarcity of hospital assistants seems to be one of the principal difficulties in connexion with the carrying on of Government charitable dispensaries of the Central Provinces and Berar. New dispensaries have been opened and continue to be opened, but more hospital assistants are urgently needed. The value of medical scholarships was raised in 1905, but still considerable difficulties are experienced in obtaining a sufficient number of candidates for the hospital assistant service. Possibly the difficulty will be obviated when the Government of India has decided what to do in regard to the improvement of the pay and prospects of hospital assistants, a subject which is at present under its consideration. The number of patients attending the hospitals is increasing, but not in proportion to the large number of new dispensaries opened. This is attributed to the prevalence of plague, which deterred people from resorting freely to dispensaries, though the feeling against attendance at dispensaries during the epidemic of plague is said to be nothing like as strong as it used to be a few years ago. Of the principal diseases treated malarial fevers head the list, but there is an appreciable decrease in the number of these cases. An ominous feature during the last three years has been the growing number of tuberculosis cases for treatment and it is feared that this disease is becoming more prevalent. A pleasing illustration of the warm regard felt by old officers of the provinces for the people among whom they have worked is afforded by Brigade-Surgeon Law and Mr. W. Brittain Jones, a former chief commissioner of the Central Provinces, having sent donations of Rs.10,000 and Rs.5000 respectively for the dispensaries. It is regarded as disappointing, however, that the contributions to dispensaries generally have not increased proportionately to the rapid growth in the material prosperity of the provinces.

Suggestions for Sanitary Reform.

Sir John Hewett has taken up the question of sanitary reform for Allahabad, Cawnpore, and Lucknow, and called attention to the high infantile and fever mortality in the United Provinces. It is high time for the educated classes, zamindars and other rich people, to come forward and assist the Government in its endeavours. A Sanitary Association might, for example, be formed at Allahabad on the lines adopted at Bombay. Before this is done local medical practitioners, Government surgeons, and assistant surgeons will have to begin to give lectures on sanitation and hygiene in English and Hindustani on subjects such as care and management of infants, causes, prevention, and cure for fevers, plague, and so on. Societies for the prevention of infantile mortality might also be formed in connexion with the Sanitary Association, and its accounts kept separate for supplying good milk to the infants of the poorer classes free or at moderate cost. The municipalities of Lucknow, Cawnpore, and Allahabad, with the assistance of the rich public, ought to set up shops for supplying good milk free to poor infants first where mortality is highest, and then for the general public, if they desire it, at the usual rates. Ladies ought to come forward to assist their poor Indian sisters by visiting their houses and teaching them how to take care of infants, and giving them good milk free or at very moderate cost. They could also teach the principles of sanitation in their own language to an assembly of ladies. As regards fever, it is suggested that a fever fund should be started. Arrangements might be made at the village post office, or with the head man of a village, to sell a packet of five grains of quinine at one price (¼ anna) as in done in other presidencies; a machine for making tablets might be ordered and quinine powder and quinine tablets given free to the poor in cities and villages. The rich seigneur struggling for the foundation of a new nation; the priest faithful unto death, labouring for souls; the soldier freely shedding his blood for the honour of his flag; the statesman spending his energies in work for the common weal —these and a hundred more scenes rise before our eyes.

Such thoughts fill the mind with vivid pictures of the past; it is meet that we should dwell upon them. The eyes of the world were turned with warm sympathy to Canada while you recently celebrated the third centenary of the foundation of Quebec by Champlain. Well-nigh four centuries have elapsed since Cartier called the beautiful ridge near which we stand Mount Royal, "and hence the name of the busy city which now holds the site of the vanished Hochelaga." A hundred years passed away before your city was founded—years of conflict with foes without and foes within; of undaunted labours for the creation of a new France; of success and failure in the great schemes of conquest. Amongst the great names which will for all time hold a place on the scroll of fame there will assuredly be none more free from fear or reproach than that of the intrepid and lofty being who planted your fair city. Well has the historian said: "The spirit of Godfrey de Bouillon lived again in Chomedy de Maisonneuve."

To turn from general topics to those which are more nearly allied with the object of to-day, a glance may be cast at the rise and growth of the University. Its far-seeing founder died in 1813, and eight years afterwards a charter was obtained for its erection. A teaching staff was appointed in 1823 and, although many of the posts were nominal, the healing art was from the first represented, Thomas Fargues, a graduate of Edinburgh, being elected in that year as professor of medicine. The "House of Recovery" was opened for the reception of patients in 1818, when T. P. Blackwood was appointed medical officer. Three years later, in the same year which saw the foundation of the University, the Montreal General Hospital was instituted, and the first medical officers were Robertson, Stephenson, Holmes, Caldwell, and Lœdel, who organised themselves as a teaching body under the name of the Montreal Medical Institution, and began to give systematic instruction in 1824. The members of this teaching body entered the McGill University as its medical faculty in 1829, and that no time was lost receives abundant proof from the fact that in 1833 the degree of Doctor of Medicine was conferred upon William Logie, who was the first graduate of McGill University.

It is very pleasant to know that amongst the distinguished group of men who formed the pioneers of medical education in Canada several were graduates of my own university. Stephenson, Holmes, and Robertson studied and graduated in Edinburgh; the origin of McGill University on its medical side is therefore connected with "Modern Athens," and its early teachers brought to Canada the methods of the sagacious Whytt and the philosophic Cullen, as well as the spirit embodied in that wonderful academic succession furnished by the celebrated families of Gregory and Monro.

To one conning the memorials of your early past it is a source of much interest to be able to trace the homes of medicine in this great Dominion. Thus it is that the drawing of the General Hospital, as it was in 1830 in "Hochelaga Depicta," is to me full of interest, whilst the painting by Lamb of Burnside House, showing how it nestled at the foot of the mountain in 1843, furnishes a historic link in the academic chain.

It would be tedious to you, who know the various steps by which the University grew from its picturesque birthplace at Burnside till it finally reached the superb site it now holds near the old home of its founder; to those like myself, pilgrims from the motherland, there is a fascination in tracing out the successive stages of its development and in recognising how similar the mode of growth has been to that which may be seen in the old world. In the course of this development it is a very agreeable fact that the academic ties with the old country are becoming closer instead of weaker. Without dealing with such as unite Montreal to the universities of the rest of the United Kingdom, a word or two may be allowed as to the present links between Canada and Scotland. Your Chancellor holds a like position in the Northern University, situated between the Dee and the Don; there, as here, he has so fostered the growth of learning and inquiry as to merit the title of a modern Mæcenas. That many years may yet be vouchsafed to him in which he may continue his beneficent endeavours for the advancement of education is a prayer as frequently and as fervently offered on the shores of the North Sea as on the slopes of the mountain. And in this connexion let me add that the kinsman and colleague of your Chancellor, who along with him not only founded and endowed your beautiful hospital but aided the development of the McGill University by munificent gifts, must be likewise regarded as a large-hearted benefactor on both sides of the Atlantic.

Some years ago you carried away the head of one of the colleges belonging to the University in the "grey old town" to preside over your labours, while we who are connected with that ancient seat of learning have within the last few weeks spirited away one of the most brilliant of your younger colleagues. Such interchanges are fraught with far-reaching influences for good. We have many other ties between us. The names of Osler, Roddick, and Shepherd, to mention only those connected with the medical faculty, are inscribed on the rolls both of Montreal and Edinburgh. In the other faculties there are also bonds of union with many of the universities of the United Kingdom, and we are therefore not merely united by the ties of sympathy but by those of personal connexion.

The commonwealth of learning throughout the world shared the grief of the University in the loss sustained by the medical faculty through the lamentable fires which destroyed the results of many years of labour, but observed with delight the dauntless energy with which you at once set to work to repair the damage and to replace what had been swept away. The new buildings which are arising like a phœnix, as the late Dean has well put it, from the ashes of their predecessors, are an evidence of the indomitable spirit with which the University is instinct.

It would not become me at this time to dwell upon the achievements of the University in the varied walks of knowledge. The special matter to which it is my wish to direct your attention will afford an opportunity of showing that in those fields best known to me yeoman work has been done by her children. But there is one subject to which in common fairness you will allow me to refer.

About two years ago certain changes in the blood taking rise in affections of the intestines, which had till then only been described by three workers in the Netherlands, were found by Carstairs Douglas and myself to be not merely due to the presence of a bacillus in the bowel, whence toxines were absorbed into the blood, but were found to be produced by the actual entrance of the microbe into the blood, where it multiplied and poisoned the very springs of being. We felt a little glow of pleasure in having, as we thought, added a new chapter to the life-history of bacteria—one which held out, moreover, the promise of practical usefulness; our results, however, had been, unknown to us, forestalled by other observers. About a year before our work was done identical results had been obtained in the wards of the Montreal General Hospital by Blakadder with the assistance of Gillies and Duval. In a group of symptoms similar to those which engaged our attention they discovered the bacillus coli in the blood. It is a bounden duty as well as a sincere pleasure to make it quite clear that this discovery belongs to the banks of the St. Lawrence and not to the shores of the Forth. The reason of our ignorance of the Montreal results lay in the fact that those interesting observations were not placed on record until last year, and we had in consequence no means of learning the valuable facts before we published our own later investigations. In the light of what we now know it is a great satisfaction to be able to award the palm to those who deserve it. Their researches form a fitting termination to the careful investigations carried out, in this university also, by Charlton, working under the supervision of Adami.

The comparison of the past with the present affords us the best means of guiding future advances. From the failures no less than the successes of ourselves, as well as of those who have gone before us, we are enabled to discern the most fruitful paths of inquiry and are led to shun the pitfalls which have hindered effort in the past. In other words, our footsteps in the present require to be guided by the light of the past, so that the future may bring with it fruits meet for progress.

In looking about for some particular subject which might usefully occupy our attention to-day it has seemed to me advisable to take some matter with which my own work has rendered me specially conversant. The now chosen is a tion, and adulteration of food products. To this end the association appointed a committee to prepare a bill founded upon the determinations of the Joint Standards Committee and which shall be formulated with a view towards uniform requirements throughout the several States. In the dual form of Government in this country laws adopted by the Federal Government can affect only matters of interstate commerce and therefore the real regulation of foodstuffs must eventually rest with the various States. The effort of the association to secure uniform and effective State legislation is on this account of the first importance and highly commendable.

Resignation of Dr. William P. Spratling, Superintendent of the Craig Colony for Epileptics.

The Craig Colony for Epileptics is about to suffer a severe loss by the retirement of its superintendent, Dr. William P. NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Defective Eyesight among the Parsis.

In his recent investigation into the condition of the eyesight of Parsi students and school children during the past year Dr. [illegible], the honorary surgeon of the [illegible] Wadia Parsi Ophthalmic Hospital, finds that defective vision is alarmingly prevalent among them. The most unobservant person in taking a walk in Bombay cannot but be struck by the number of young Parsis decorated with spectacles, but Dr. [illegible] says that these represent only a fraction of the defective sight which actually exists. The majority of those who need glasses, he says, cannot obtain them for want of money or go without through neglect, to the further injury of their eyes resulting in pain and a handicap through life, and he appeals for funds to supply poor Parsis with spectacles free of charge. While this call deserves a general response it is much more necessary to take steps to prevent the further injury of the eyes of the young. The Germans are a notoriously short-sighted people since they took to education owing chiefly to the illegible character of their language and it is probable that the bad printing and small type used in Gujarati primers are also responsible for this trouble among the Parsis. More probably, however, the trouble is often caused by the learning of English from types insufficiently large at a time early in school life. At whatever age the learning of a language is begun it should be prosecuted at first by means of the big type made for little children, for the strain on even an adult eye of reading unfamiliar characters is many times greater than that of reading characters of the same size which have grown familiar. Intelligently conducted optometric tests should be made of the Gujarati characters, and if found injurious in their present form they should be modified, printed big, or abolished altogether.

Veterinary Work in the Central Provinces.

From the annual report of the veterinary department of the Central Provinces we learn that the conversion of the people in favour of the inoculation of their cattle against rinderpest has been in some places most striking. Pending the introduction of a new scheme in 1903 a small staff of veterinary assistants, paid from provincial funds, has been organised. These men were generally employed on inoculation and in their work they had a marked increase in the number of inoculations and the department's growing popularity with the people. Hitherto inadequate recruitment has been one of the main obstacles to advance, and the closing of the Lahore Veterinary School and of the junior class at the Bombay College has increased this difficulty. With the provincialisation of the department which the new scheme involves the scale of pay of veterinary assistants will also be raised, and it is hoped that the improvement in prospects will attract more candidates of a suitable class. Of course, the activities of the department are by no means confined to inoculation work. Cattle-breeding farms have been established and bulls are distributed to stock-owners with the object of improving local breeds of cattle. This latter measure has not been so successful as anticipated and the question of altering the system is under consideration.

Central Provinces Medical Department.

The scarcity of hospital assistants seems to be one of the principal difficulties in connexion with the carrying on of Government charitable dispensaries of the Central Provinces and Berar. New dispensaries have been opened and continue to be opened, but more hospital assistants are urgently needed. The value of medical scholarships was raised in 1905, but still considerable difficulties are experienced in obtaining a sufficient number of candidates for the hospital assistant service. Possibly the difficulty will be obviated when the Government of India has decided what to do in regard to the improvement of the pay and prospects of hospital assistants, a subject which is at present under its consideration. The number of patients attending the hospitals is increasing, but not in proportion to the large number of new dispensaries opened. This is attributed to the prevalence of plague, which deterred people from resorting freely to dispensaries, though the feeling against attendance at dispensaries during the epidemic of plague is said to be nothing like as strong as it used to be a few years ago. Of the principal diseases treated malarial fevers stand the first, but there is an appreciable decrease in the number of these cases. An ominous feature during the last three years has been the growing number of tuberculosis cases for treatment and it is feared that this disease is becoming more prevalent. A pleasing illustration of the warm regard felt by old officers of the provinces for the people among whom they have worked is afforded by Brigade-Surgeon Law and Mr. W. [illegible] Jones, a former chief commissioner of the Central Provinces, having sent donations of Rs.10,000 and Rs.5000 respectively for the dispensaries. It is regarded as disappointing, however, that the contributions to dispensaries generally have not increased proportionately to the rapid growth in the material prosperity of the provinces.

Suggestions for Sanitary Reform.

Sir John Hewett has taken up the question of sanitary reform for Allahabad, Cawnpore, and Lucknow, and called attention to the high infantile and fever mortality in the United Provinces. It is high time for the educated classes, zemindars and other rich people, to come forward and assist the Government in its endeavours. A Sanitary Association might, for example, be formed at Allahabad on the lines adopted in Bombay. Before much is done local medical practitioners, Government surgeons, and assistant surgeons will have to begin to give lectures on sanitation and hygiene in English and Hindustani on subjects such as care and management of infants, causes, prevention and cure for fevers, plague, and so on. Societies for the prevention of infantile mortality might also be formed in connexion with the Sanitary Association, and its accounts kept separate for supplying good milk to the infants of the poorer classes free or at moderate cost. The municipalities of Lucknow, Cawnpore, and Allahabad, with the assistance of the rich public, ought to set up shops for supplying good milk free to poor infants first where mortality is highest, and then for the general public, if they desire it, at the usual rates. Ladies ought to come forward to assist their poor Indian sisters by visiting their homes and teaching them how to take care of infants, and giving them good milk free or at very moderate cost. They could also teach the principles of sanitation in their own language to an assembly of ladies. As regards fever, it is suggested that a fever fund should be started. Arrangements might be made at the village post office, or with the head man of a village, to sell a packet of five grains of quinine at one pice (a farthing), as is done in other presidencies; a machine for making tablets might be ordered and quinine powder and quinine tablets given free to the poor in cities and villages. The man still further advanced the subject and with these investigations the first chapter of the anatomical explanation terminates. Eight years afterwards Ewald returned to the link binding auricle and ventricle in the frog, and shortly afterwards Retzer, Bræunig, and Humblet extended the observations. These workers paved the way for the elaborate investigations of Tawara, who carried out a most valuable research fully demonstrating the origin and ramifications of the structures by which the anatomical gaps separating the different portions of the heart are bridged over. Keith has more recently, in a manner as lucid as it is luminous, further extended these remarkable investigations.

The researches of Tawara have shown that the auriculo-ventricular bundle is only a part of a great system; it descends on the interventricular septum, ramifies throughout every part of the ventricular walls, and is continuous with the system of Purkinje fibres. The papillary muscles are brought into especial relation with the system and this very interesting point throws a vivid light upon the important observations made on the functions of these structures by Roy and Adami, to which the latter has again returned more recently.

Keith has illuminated the subject, as he usually does, by the brilliance of imagination as well as the result of labour. He described the musculature of the sinus as being freely continuous with that of the auricular canal and auricular appendix. In searching for a clearly differentiated system of fibres within the sinus, which might serve as a basis for the inception of the cardiac rhythm, he discovered a peculiar structure surrounding the arterial circle at the junction of the sinus and the auricle. The structure closely resembles that of the auriculo-ventricular bundle, consisting of an intimate network of pale, undifferentiated fibres with well-marked nuclei. This structure contains numerous nerve cells and nerve fibres. Although the mass is undoubtedly muscular in its main structure yet the nerves in the neighbourhood of the vena cava enter into very intimate connexion with it, so that Keith feels justified in stating that a peculiar neuro-muscular junction occurs at this point.

As assisting us in understanding the functions of the heart, the researches of MacCallum on the muscular connexions of the two ventricles, of Keith upon the special anatomy of the heart, of Porter on the relation of blood-supply to cardiac activity, and of Henderson upon ventricular movements, are far-reaching in their results and enable us more fully to apprehend the questions arising in connexion with this subject. The first has shown most distinctly that the ventricles are composed of a simple long band of muscle beginning and ending with a tendon. It has its origin in the connective tissue of the auriculo-ventricular junction on one side of the heart; it passes around the outer wall of that side and reaches the ventricular septum whence it goes on to encircle the outer wall of the other ventricle and finally terminates in the tendinous cords of that side. It is probable that the fibres of the auriculo-ventricular bundle enter into direct relation with the centre of this long scroll.

Some of the results obtained by Keith have already been referred to, but the observations which he has made from the standpoint of comparative anatomy deserve to be recalled. He has shown that the sinus venosus, the auricular canal, the auricle, the ventricle, and the bulbus, are all represented in the mammalian heart, and he has been able not merely to trace these primary divisions but to show how in the evolution of the heart in the higher mammals these various parts have been modified to suit the requirements of development. The results of the investigations of Porter and of Henderson have been of the greatest service to us in our clinical work on disturbances of the heart muscle.

Turning to the results of experimental physiology as directed more particularly to our subject, we have to acknowledge a deep debt of gratitude to certain distinguished observers. First, again, physiologically as well as anatomically, comes the name of Gaskell, in the epoch-marking work to which reference has already been made. He pointed out the existence of natural block at the auriculo-ventricular junction, and further showed that a more or less complete stoppage could be produced either by section of the auricle or by increase in the natural block. In this way he was able at will to interrupt the passage of impulses more or less completely. His, from a number of experimental investigations, showed that interference with the conduction of impulses could be produced by section of the auriculo-ventricular band. It is, however, particularly to Erlanger that we are indebted for a study of this important subject. By his ingenious method of experimentation the auriculo-ventricular bundle could be subjected to varying degrees of pressure, and he has been able in this way, as is now widely known, to produce at will every degree of partial or complete blocking of impulses. From the experiments of Gaskell, His, and Erlanger it is clear that the upper parts of the heart possess the quality of rhythmicity in a higher degree than the lower; that the rate of the heart is determined by the upper and more rhythmical portions, and if the lower and less rhythmical are separated from the upper and more rhythmical portions, the lower part may assume a rhythm of its own. From two very interesting studies by Hering and by Erlanger and Blackman, which have recently made their appearance, the relative rhythmicity, excitability, and conductivity of the different portions of the heart are most clearly brought before us.

Pathological evidence has not been long in following upon the heels of anatomical and physiological investigation. Stengel, Jellick Cooper, and Ophuls in America, and Keith and myself in Europe in the same year, have put on record instances of disease of the auriculo-ventricular band from cases of heart block. In some of these cases the structural alteration was a gumma of the interventricular septum; in others it was a simple fibroid change without any very obvious cause. In one instance which aroused a most widespread interest, seeing that it occurred in the person of one of the most venerable and distinguished physicians of the British Isles, the change has been found to be of the nature of a calcareous infiltration.

Such, then, are the main lines of the explanation of these interesting appearances. When we seek to inquire which of the five distinct functions of cardiac activity are involved, we discover that it is easy to demonstrate the implication of two of them. Rhythmicity in itself is not disturbed, for the auricular pacemaker pursues its even tenor; contractility is in no way lessened, since the work of the heart may be in no way diminished; tonicity, it need hardly be said, is not a function necessarily involved in this group of symptoms, although undoubtedly, seeing we deal with senile heart in many instances, this property may be lessened. The cause of the appearances lies as a rule in diminished conductivity, the auriculo-ventricular bundle being so damaged as to diminish the function or even to abrogate it. Some interesting tracings from a patient long under my care have, however, shown that the function of excitability may be disturbed, and this may therefore be partly responsible for the symptom. Hay has especially devoted attention to this aspect of the subject.

Is it possible to get beyond this point? Can we peer further into the darkness which surrounds the real cause of these varied appearances? In other words, are we able to say how the heart is endowed with such functions and in what way they are disturbed?

We may fearlessly assume that the entire realm of nature is freely open to our inquiries. The Venusian bard, whose verses have ever since the revival of learning been the solace of such a multitude as no man can number, is assuredly astray when he sings, "Nec scire fas est omnia." But while we claim the right to examine every natural phenomenon we are led to acknowledge that some facts are within our reach while others are beyond our ken. In the quest of truth it is wise to bethink ourselves of this distinction between the attainable and the unattainable. Above all it is our duty not to be dogmatic as regards matters which we cannot know. It was Huxley who said that "the assertion which outstrips evidence is not only a blunder but a crime." Some of the appearances which have been brought before you to-day have furnished an example of speculation in the region of the unattainable; of playing with words rather than working with things. Within recent years much time has been wasted in futile assertions that the five great functions of cardiac activity recognised by Gaskell are entirely due to inherent properties of the heart muscle, or, as it is put, are of myogenetic origin. According to this view, or, as it would be better to put it, according to these views—for the opinions of the myogenetic school are often so contradictory as to cancel each other—the heart lives and moves and has its

Gilruth has been recognised here as one of our leading pathologists. He has for several years been head of the veterinary branch of the Agricultural Department, and the high state of efficiency of that service is entirely due to him. In New Zealand we have a system of meat inspection which could not be bettered. Every shoulder of mutton, every frozen kidney, every pound of boned meat is marked with the stamp of a qualified veterinary surgeon. This has been his work and his alone. In addition to this he has made many original observations on cancer, Winton disease in horses, and blackleg in cattle. He has, since the inception of the Health Department, acted as pathologist and has rendered most valuable help with respect to those diseases which are common to man and the lower animals. Without doubt New Zealand is losing one of its most accomplished experts in bacteriology and microscopy. He has been appointed professor of animal pathology at the University of Melbourne at a salary which it has been stated is the highest ever paid to a veterinary surgeon.

Visit of the American Fleet.

The visit of the "Great White Fleet" to the beautiful harbour of Auckland has been of interest to the medical profession as to all classes of the community. Never has there been seen in British waters south of the Line such an array of battleships. With splendid precision stately engines of war steamed into the famed Waitemata ("waters of peace"). Though they had met with storm and stress on their journey from Honolulu, the 16 great battleships steamed to their anchorage and dropped anchor each within ten feet of its allotted space. Here, while we have a "local option" sort of Contagious Diseases Act, syphilis bars a person from oversea from landing, and the chief health officer was instructed to board the flagship and lay this, among other matters, before the fleet surgeon of the American Squadron. New Zealand being the first British point of land that the Fleet touched, naturally wished to further its convenience in every way, and so arrangements were made whereby the hospital statements from the various ships were sent on board the flagship and examined by the chief health officer and Mr. E. W. Sharman, the port health officer of Auckland. There have been singularly little sickness and few accidents during the long cruise. The hospital ship was of especial interest. For the first time in the history of any navy a medical man was captain, and well and worthily did Surgeon Stokes fill that position. You may remember that much disturbance was occasioned in the purely combatant branch when it was suggested that the hospital ship should be commanded by a surgeon. The experiment has been amply justified. Everything has gone smoothly and the work done has been of the highest order. A hospital ship must hereafter be a certain part of a fleet which goes far from home waters. One instance will suffice to show its usefulness. An outbreak of diphtheria took place on the *Nebraska*. Within three days swabs had been taken from the throats of the 1200 occupants of that ship, and as a result of the microscopical examination 82 men were transferred to the hospital ship and the outbreak was stopped right away. The dollar which America handed over to Miss Gould for this splendidly equipped ship was undoubtedly well spent, and in this truly the "Great White Fleet" has taught us a lesson.—One of the most pleasing of the many functions held in honour of our American visitors was the supper given by the Auckland branch of the British Medical Association, under the presidency of Dr. H. M. Inglis. The utmost good-fellowship prevailed and by general consent Dr. W. C. W. McDowell's admirable treatment of the toast of the evening formed without doubt one of the finest speeches of the week. In proposing the health of Fleet-Surgeon [illegible] and the other medical officers of the Fleet, he called special attention to the great preventive work in tropical medicine in which naval surgeons had of late years borne so prominent a part. He paid a full tribute to some of the great names in American surgery and wound up with an eloquent peroration in which he said:—

> Last Sunday morning the Union Jack and the Stars and Stripes floated side by side to welcome the Fleet's arrival, but now, at the close of the week, after such happy intimacy, we realise that the officers and men of the American Navy have drawn the flags nearer together; yes, have, indeed, succeeded in entwining them together into a fast and firm "sailor's knot."
>
> I now call upon you to charge your glasses and drink to the health of the surgeons of the Fleet, the pioneers in this great work, and let us also toast to the dawning of the day when, with a union in reality and a [illegible] the "sailor's knot" will be [illegible] "lover's knot" as the symbol of the relations between the two branches of the Anglo-Saxon race, a mighty dignity in unity, a power making for liberty, equity, and fraternity among the nations of the earth.

Never was the force of the Indian proverb, as Kipling has given it to us, more aptly illustrated than on that evening: "I met an hundred men on the road to Delhi and everyone was a brother."

August 21st.

Obituary.

SIR ARTHUR VERNON MACAN, M.B., M.Ch. Dub., F.R.C.P. Irel.,

KING'S PROFESSOR OF MIDWIFERY, TRINITY COLLEGE, DUBLIN, ETC.

THE death of Sir Arthur Vernon Macan, which took place on Sept. 26th at his residence, 53, Merrion-square, Dublin, has deprived the Irish metropolis of one of its prominent practitioners. The deceased gentleman was the eldest son of the Hon. John Macan, Q.C., who was for many years a judge in the Irish Court of Bankruptcy; and he was born in Dublin in 1843, so that he had reached the age of 65 years. He received his collegiate education at the University of Dublin, in which institution he passed through a distinguished academic career and graduated in 1863. Having chosen medicine as a profession and selected, almost from the outset, the specialty of obstetric surgery and gynæcology in which he came in time to play so active and distinguished a part, he took the diploma of the Rotunda Hospital at an early stage; and after having obtained the University degrees of M.B. and M.Ch. at his alma mater he proceeded to perfect his post-graduate studies at Berlin and Vienna. He was so far favoured by professional fate as to enter the portals of the healing art at the precise period at which the epoch-marking Listerian revolution was beginning to work out its great reformation in surgical practice. He always retained his close association with the great Rotunda maternity, and when he returned to its wards as assistant master, and afterwards as master, it was in the way of conspicuous approach on the crest of the wave of the antiseptic movement. He enjoyed the unique privilege of leading the anti-microbic crusade into the greatest lying-in institution of the British Empire; and it need hardly be added that the triumph of a campaign which was necessarily and inevitably successful secured the name and fame of Dr. Macan for the whole of his subsequent professional career. His great physical activity enabled him to carry out an amount of muscular and mental exertion which would have overtaxed the resources of most. And his emphatic force of character proved an effective mainspring in all his professional and social movements. Thus he was enabled to face and to overcome direct opposition and collateral obstruction to movements of reform with less waste of valuable time (and diplomatic courtesy) than would have been found necessary or thought desirable by organisers of less natural vigour. Dr. Macan was elected a Fellow of the Royal College of Physicians of Ireland in 1877 and became the President of that institution in 1902-04. Dr. Macan's Mastership of the Rotunda Hospital constituted—in its usual septennial course—a genuine triumphal progress of professional practice; by the establishment of the inestimable boons of antiseptic cure and aseptic prevention in his special departments of obstetrics and gynæcology the horrors of puerperal sepsis were once and for all "laid" under his *régime*, in the great maternity of the Irish metropolis; and there are but few items of the history of the profession—or, indeed, of the human race—which better deserve the most grateful recognition of contemporaries and of posterity.

The late Sir Arthur Macan enjoyed not only a prominent career as a practitioner and pioneer of applied science, but also as a hospital and lecture-room teacher. He lectured on midwifery and obstetrics for a number of years at the Carmichael School of Medicine, from which he passed to the corresponding chair in the University of Dublin. This latter position carried with it appointment to the staff of Sir Patrick Dun's Hospital, to which institution he thus became obstetric physician and gynæcologist. The prominence of his professional position and the solid value of his contributions to professional knowledge led to the successive receipts of other testimonials of the recognition of his brethren, such as the presidency of the great deal has been attempted) has been on right lines; and if it has not, to consider how we should rectify our past action, and in what directions, in which we may have hitherto fallen short of our duty, we should now endeavour to extend our efforts. The subject is a vast one; few, if any, of the activities either of the individual or the State are not affected by it; and anything that I can say can but touch the fringe of the problems that you will have to consider, and can only, I fear, be directed towards impressing upon you the magnitude of the task you are called on to undertake without suggesting to you the means of overcoming it.

In the resolution summoning this conference stress was laid on the fact that it is impossible to make any certain comparison between past and present vital statistics. The actual record of the number of births and deaths has become much more accurate during the past quarter of a century, but except in the case of a few well-known diseases the village watchman—the reporting agency in the rural tracts—cannot be trusted to return the cause of death correctly. We can indeed rely on his reports regarding small-pox and cholera being fairly accurate, but he cannot discriminate between diseases the symptoms of which are accompanied by a rise of temperature, and the deaths attributed to fever doubtless include large numbers due to pneumonia, tuberculosis of different kinds, and many other diseases. Again, in the six years between 1902—when plague took hold of the province—and 1907, over a million deaths were reported to have been caused by it. How many really due to it were registered as having been caused by some other disease? Incomplete as the record of the number of deaths attributed to it in the past six years must be, it is equivalent to the normal death-roll within the province for more than six months. This factor of itself precludes close comparison between the figures of the past few years and those of less recent periods, but the former taken by themselves are so appallingly high as to demand the closest scrutiny of all who have the country's welfare at heart.

Speaking generally, the death-rates recorded in the province in recent years, both in urban and in rural tracts, are nearly three times as high as in England and Wales. It is estimated that in India nearly one out of every ten of the population is constantly sick and a person who has escaped the diseases and dangers of childhood and youth and entered on manhood or womanhood has an expectation that his or her life will extend to only 68 per cent. of the time that a person similarly situated may be expected to live in England. Infantile mortality in the province is nearly twice as great as it is in England. I quote these comparisons to show how backward we appear to be in the protection of life as compared with the mother country, but at the same time you will all realise how misleading it would be to judge our vital statistics by results in Europe and understand how vain it is to hope that we can ever attain to the standard that has been achieved in the West. We should never forget that in this province the conditions of life, which depend on the climate and connected matters, are in some respects specially unfavourable to health and longevity. The whole area of the province is 112,000 square miles. Between one-fifth and one-sixth of this is situated in the Himalaya, with a sparse population of a little over one and a half millions. The highest density per square mile—it is only 86—occurs in the Almora district. With a splendid climate and a very sparse population comparatively little remains to be done except to induce the people to pay more attention to the cleanliness of the village sites and their immediate neighbourhood. At the same time the hilly tracts are liable to occasional epidemics of cholera of great virulence which are much assisted by the practice of the hillmen of burying in running streams the victims of epidemic disease instead of following their usual practice of burning the dead. But, speaking generally, the conditions of life in the hills are much more favourable than in the plains. The area of the plains extends to 93,000 square miles and contains a population of 46,000,000. Most of this area is flat and liable to be waterlogged during the rainy season. The mean annual rainfall is between 37 and 38 inches. The monsoon of three months is wedged in between a period of intense heat all over the province and a period of milder weather which at some places merges at night into one of intense cold. The difference between the maximum temperature in the sun and the minimum temperature in the shade within a period of 24 hours sometimes exceeds 120°; that between the maximum and the minimum temperature in the shade is often 40 or more within the same period. These extraordinary variations in climate and temperature call in themselves for special precautions. They are aggravated by the conditions under which the people live, some of them inseparable from the agricultural operations of the different seasons or for other reasons unchangeable, others the direct or indirect result of neglect of recognised sanitary canons and susceptible of improvement. The houses in which the people live, whether in town or country, are seldom set on a high enough plinth. The average population and the number of houses to the square mile are higher than in any other part of India. The urban population, aggregating a little over five millions, number on the average 13,600 to the square mile, and rise in Cawnpore generally to 37,500 and in parts of the city to over 64,000 to the square mile. What this means can be imagined if you will reflect that in London with its buildings of many storeys the density is but 37,000 and that in Cawnpore the number of houses with more than one storey is comparatively small. The average density of the population in the villages is 427 to the square mile. It rises to 791 in the Ballia district, and exceeds 500 in 22 districts. The average number of persons per house (which frequently consists of two rooms or even of only one) is 5·3 in important cities and 5·5 in the rest of the country. It is estimated that the average superficial area per head of the population is something like 10 square feet, and the breathing space—150 cubic feet—just half what is required in common lodging houses in England. In the rainy season high crops are grown right up to the habitations of the villages. When the spring crops are being cultivated the same soil is, wherever possible, irrigated. Little or no care is taken to arrange for the removal of refuse in the rural tracts. The village pond or tank is the receptacle of filth of every kind; its water is regularly consumed by cattle and even by human beings. The offices of nature are performed in the fields just outside the houses, and the water of the wells is often polluted by the subsoil drainage into them. Flies are always prevalent and at certain times of the year become a pest. They have much responsibility for the communication of disease and are assisted by numerous other insects. Even this is not a complete category of the hindrances to the public health in the rural tracts, but it is sufficient to show how great are the difficulties in bringing about a salutary change.

I have already sounded a warning note against attaching too much importance to comparative vital statistics in this country but we must necessarily in approaching the consideration of all questions connected with sanitary improvement keep such statistics before us. The reported mortality per 1000 among the general population works out at the following rates in the last quarter of a century:—

1882–91	32·72
1892–1901...	32·56
1902–07 (including plague)	39·01

In the same three periods the mortality in jails has been 25·5, 27, and 16·6 respectively. The difference is marked particularly in the last period. In jails everything is done to avoid overcrowding, each prisoner being allowed a minimum of 36 square feet of superficial area and 648 cubic feet of breathing space; large sums have of recent years been spent on improved barrack accommodation and ventilation; there is an almost complete freedom from epidemics; the death-rate is not augmented by infantile mortality; food, water, and sanitation are good, and the hours of work regular. We cannot ever hope to get the death-rate among the general population down to the figure that has been attained in jails, but between the death-rates in the jails and among the free population respectively there is a large margin which is undoubtedly capable of considerable reduction. It is towards the most effectual means of effecting this reduction that you are asked to direct your minds during the session of this Conference.

The problem that you have to consider differs very much according as it is directed towards the amelioration of the conditions of life in rural or in urban tracts. The number of villages in the province is 105,068 and the average population of a village is just over 400; 37 per cent. of the rural population inhabit villages with a population of less than

The Emperor of Japan has sent a donation of £500 to the Seamen's Hospital Society in recognition of the assistance rendered to Japanese subjects by the Dreadnought Hospital at Greenwich.

The opening meeting of the Chelsea Clinical Society will be held at the Chelsea Dispensary, Manor-street, King's-road, on Wednesday, Oct. 14th, at 8.30 P.M. The President, Mr. A. F. Penny, will give his opening address on "The Rise of the General Practitioner."

Guild of St. Luke.—The annual festival service of the Birmingham Ward will be held in the Cathedral Church, Birmingham, on Monday, Oct. 19th, at 5.30 P.M., when the sermon will be preached by the Rev. P. N. Waggett, M.A. Medical practitioners are cordially invited to attend.

The Hospital for Sick Children. — The winter session of lectures at the Great Ormond-street Hospital will be opened on Thursday, Oct. 22nd, at 4 P.M., when Mr. T. H. Kellock will give a demonstration on selected cases in the surgical wards. On Oct. 29th, at 4 P.M., Dr. F. E. Batten will give a demonstration on selected cases in the medical wards.

Royal Eye Hospital, Southwark. — The winter session of the post-graduate course of instruction in ophthalmology will commence on Wednesday next, Oct. 14th, at 8 P.M., when Mr. L. Vernon Cargill, F.R.C.S., surgeon to the hospital, will deliver the opening lecture, the subject of which will be "The Importance to a General Practitioner of some Practical Knowledge of Ophthalmology." All medical men interested in the subject are invited to attend the lecture.

Museum Demonstrations at the Royal College of Surgeons of England.—In addition to the usual course of Hunterian and other lectures to be delivered during the present winter session the Council of the Royal College of Surgeons of England has arranged a series of demonstrations in the theatre of the College at which specimens from the museum will be shown and their bearing on general and surgical pathology discussed. The first demonstration of the series is to be given on Friday next, Oct. 16th, at 5 P.M., by Dr. Arthur Keith, "On Specimens Illustrating Malformations of the Rectum and Anus"; and the second on Monday, Oct. 19th, at 12 noon, by Mr. S. G. Shattock, on "Hypertrophy." The subjects and dates of the other demonstrations may be seen in our advertisement columns and from the notices posted at the College and medical schools. These demonstrations are open to all medical men and senior students on presentation of their cards.

School of Pharmacy.—The seventy-seventh session was opened at 17, Bloomsbury-square, on Sept. 30th, Mr. J. Rymer Young, the President of the Pharmaceutical Society of Great Britain, being in the chair, supported by a large attendance. Professor Greenish, the dean, read his report which showed a very high percentage of successes gained by students of the school in both the major and minor examinations in pharmacy. He then enumerated the higher academical distinctions recently gained by past students and announced that 43 students had already entered for the full minor course for this session. He alluded to the recent and prospective improvements in the laboratory accommodation of the school. The President then called upon the lecturer in botany, Mr. H. J. Jeffery, to present his report on the herbarium competition. He announced the award of the silver medal to Mr. H. V. Potter for "a carefully selected collection of plants quite representative of British flora." Mr. E. S. Peck then announced that Miss Gertrude Wren had gained the Pereira medal in pharmacy with 82 per cent. of the total number of marks. She was the first lady pharmacist to attain that honour. The secretary followed by reading the report on the Jacob Bell Memorial Scholarships which were won by Mr. W. R. Pratt and Mr. S. J. Bourn. The Salters' scholar was Mr. C. Gilling, and the Redwood scholar Miss Gertrude Wren. Mr. F. H. Lescher, F.C.S., then delivered his inaugural address upon the subject of "Commerce, Science, and Work." He touched briefly upon the history of the commerce in drugs from the days of Solomon downwards, then passed on to consider a few points of prominent scientific interest, including the liquefaction of helium and the electric fixation of atmospheric nitrogen, and concluded with a dissertation upon the paramount influence of work for success and happiness.

University of London: University College.—Entrance scholarships and exhibitions have been awarded as follows: Bucknill scholarship, 135 guineas, H. W. Davies (University College, Bangor). Epsom scholarship: J. A. Cowan. Two exhibitions, 55 guineas each: R. L. Horton and C. J. A. Griffin (University College, London).

King's College (University of London): Special Lectures in Physiology.—A course of eight lectures on the Bio-chemistry of the Brain will be delivered in the physiological laboratory, King's College, London, by Professor W. D. Halliburton and Dr. Rosenheim on Mondays at 4.30 P.M., commencing on Oct. 19th. The subjects treated will include the proteins, phosphorised constituents, cholesterin, &c., in nervous tissues, and the part played by each in health and disease. The course has been recognised by the University of London as a course of advanced lectures for the B.Sc. degree. The lectures are free to all members of King's College, to all students in any of the London medical schools, and to medical practitioners on presentation of their cards.

Association of Women Pharmacists.—The fourth annual public meeting of this association took place on Oct. 1st in the lecture theatre of the School of Pharmacy at 17, Bloomsbury-square, London, W.C. (by permission of the Pharmaceutical Society), the President, Miss Buchanan, being in the chair. Miss Buchanan opened the meeting with a few remarks on the aims of the association and its work during the year, mentioning that this year the highest honour in pharmacy, the Pereira medal, had for the first time been awarded to a woman, Miss G. Wren. Mr. J. Cantlie then addressed the meeting on Some Tropical Diseases, illustrating his remarks with lantern slides. He concluded by a few remarks on the tendency nowadays to prescribe one drug for one disease, whereas excellent results had been obtained in the past by the scientific combination of a number of drugs. Warburg's tincture, for instance, was said to contain 24 different drugs and was still widely used in India as a remedy for malaria. Mr. Cantlie was accorded a cordial vote of thanks for his lecture.

Presentation to a Medical Practitioner.—Mr. Lewis D. Alexander, M.D., C.M. Aberd., has recently been the recipient of a handsome testimonial on his attaining his semi-jubilee as medical man in Kilcreggan. He received a deposit receipt for £250 and a silver salver with suitable inscription, while Mrs. Alexander was presented with a set of sable furs. At the meeting the provost of the town presided, while Mr. Peter Donaldson, in the absence of the Duke of Argyll, made the presentation.

Tendering for Public Appointments.—The following resolution was passed unanimously at a special council meeting of the Society of Public Analysts and other Analytical Chemists held on Oct. 1st:—

> The Council of the Society of Public Analysts and other Analytical Chemists has had under consideration the practice which has been adopted recently by certain public bodies of inviting applicants for the office of public analyst to state the terms upon which they are prepared to accept such appointments. The Council is of opinion that it is against the interests of the public and degrading to the profession of analytical chemistry for appointments to be offered "on tender," and calls upon the members of the society to resist the practice.

BOOKS, ETC., RECEIVED.

Baillière, Tindall, and Cox, 8, Henrietta-street, Covent Garden, London, W.C.

- Mental Deficiency (Amentia). By A. F. Tredgold, L.R.C.P. Lond., M.R.C.S. Eng., Consulting Physician to the National Association for the Feeble-minded, and to the Littleton Home for Defective Children; Medical Expert to the Royal Commission on the Feeble-minded. Price 10s. 6d. net.
- The Bacteriology of the Eye. By Dr. Theodor Axenfeld, Professor of Ophthalmology in the University of Freiburg. Translated by Angus Macnab, B.A., B.Sc., M.B., Ch.B., F.R.C.S., Chief Clinical Assistant, Royal London Ophthalmic Hospital. Price 21s. net.

any improvement is to be effected in the health and vigour of the race.

The facts I have just enumerated are depressing enough, even if there is a crumb of comfort to be gained from the success of our efforts in effecting a reduction of the death-rate in cholera, bowel diseases, and small-pox. But hitherto we have only been looking at the death-rates, and if you will turn your attention to the birth-rates you will see reason for thinking that the efforts towards sanitary improvement made during recent years have not been altogether without fruit. Our reported birth-rate is almost the highest in India. During the period 1882-91 it exceeded the reported death-rate by 6·07 per 1000, and in 1892-1901 by 5·97 per 1000; but for the plague it would have during 1902-07 exceeded the death-rate by 8·33, but it actually exceeded it by 4·54 only. It is reasonable to argue that the more than proportionate increase in the birth-rate is to a material extent due to the improvement of the people. If the results of the sanitary measures instituted or undertaken by the Government have not been as remarkable as we could wish them to have been, this is, at all events, not due to any lack of interest in the matter. The question of sanitary reform has, indeed, been constantly before the Government ever since the report of the Royal Commission on the Sanitary State of the Army in India was published 45 years ago. The principle adopted by the Government of India as long ago as 1879 was that it was undesirable to resort to stringent legislative or administrative measures to enforce village sanitary reform, and that until the sanitary condition and healthfulness of towns had been generally brought up to at least a fair standard, and the objects of sanitary reform had become more generally understood, it would be unwise to do more than to endeavour by precept and advice, on every suitable opportunity, to secure improvement of the sources of the water-supply in villages, the systematising and rendering innocuous of the habit of resorting to the fields to obey the calls of nature, and the improvement of the surface drainage of village sites. The experience of the past 30 years has demonstrated over and over again that it is useless to attempt to dragoon the people into taking sanitary precautions. Violent remedies are of no service to sanitary progress: if advance has been slow let us hope it has been sure, since one thing of all others is certain, and that is that it never can be quick. We can never move over the people: we must move by and through them.

A Sanitary Board was created nearly twenty years ago as a consultative body for the province: it was contemplated that, when considering the sanitary requirements of a particular revenue division of the province, it should be strengthened by the addition of members to represent such division. One duty that was expected of it was that it would carry out a sanitary survey in selected parts of the province. Something much more definite than has yet been attempted seems to me necessary in this latter direction. The constitution of the board has been altered from time to time, but its working has not been successful hitherto, and my observation of its proceedings in recent years has convinced me that its system of transacting business has become more and more formal. The Government of India has determined that the time has come when the constitution and functions of the board should be reconsidered, a step which seems to me personally most desirable. In particular it is essential that the non-official community should be adequately represented on it. The Government Sanitary Department consists of a sanitary commissioner, two deputy sanitary commissioners, and a large vaccination staff. It is for consideration whether the department should not be enlarged and its functions extended. In municipalities large sums of money are spent on ill-organised and badly equipped establishments. It is proposed to constitute a sanitary service, the members of which would be utilised for service in the different municipalities. All these matters connected with establishments are among those on which your advice is sought by the Government.

Although laws will not in themselves make people follow sanitary principles, they are necessary to insure the proper fulfilment of rules with which the people have become familiar and generally recognised to be in the interest of the community generally, as well as for raising of funds and to give legal authority to acts undertaken to improve the public health. I have mentioned the Village Sanitation Act and the sanitary provisions of the Municipalities Act. There are also Acts relating to lodging-houses, to water works, and to sewerage and drainage. The Government is about to relieve small towns to which Act XX. of 1856 applies of the charges for police, and their revenues (some three lakhs of rupees = £20,000 a year) levied under that Act will be available for sanitary purposes. This change involves a change in the law and your opinion is invited as to the manner in which this should be carried out. It will also be open to you to consider whether any changes are needed in the Village Sanitation Act or in the provisions of the Municipalities Act regarding sanitary matters, or in any of the other Acts that I have just referred to.

As you are aware, the Government of India made to this Government, beginning with the current financial year, a grant of five lakhs (£33,000) of rupees a year to be devoted to sanitary improvements. I have determined to begin with an endeavour to improve the congested areas of certain of the larger towns by cutting broad roads through them. Schemes are in an advanced stage and will soon be commenced in Allahabad, Lucknow, and Cawnpore. I am also providing the Benares municipality, which has done a great deal in this direction in the past 25 years, with funds to cut a single road in the city. We hope to facilitate traffic and the perflation of air through these cities, to clear out specially insanitary areas, and to erect a few model dwellings on sanitary lines. Some people consider the erection of model dwellings at all to be a work of supererogation. I cannot agree with them, any more than with those who go to the opposite extreme and expect the State to take up the work of house building on an unlimited scale, and to arrange for a general housing of the population of towns in suitable buildings. All that we can try to do is to build a few—a very few—buildings suitable for different classes at a moderate cost, and to look to the public and builders to copy the models. Papers regarding this proposal will be placed before you. So far the great difficulty has not been overcome—viz., that of designing a sanitary house for the poorest classes at a cost which will not make its rent prohibitive. Other methods of improving conditions in towns that suggest themselves for your consideration are regulations to preserve a minimum space for new houses, to provide for building on standard plans, some form of encouragement to people whose houses are specially well kept, the strengthening of the authority of the health department and the more efficient enforcement of municipal by-laws for sanitary purposes, better markets and more supervision of the sale of articles of food and drink, and more complete drainage and paving schemes which are essential before the benefits of a filtered water-supply can be fully enjoyed. In rural areas the provision of pure water, the drainage of the village site, and attention to simple rules of conservancy are the chief requirements. Here, too, it would be well to have some definite area fixed for all new houses, and if possible to prevent excavations from being made except at a considerable distance from the village site.

Above all, throughout the country we want to teach the people to look after themselves; to educate them in the principles of simple hygiene, and to induce them to abandon insanitary habits. We may pour out money like water on sanitary improvements all to no purpose if we do not get the people to realise that they are for their good. Let us not forget that such success as has been attained in England is due to the general readiness of the people to believe that sanitary regulations, irksome though they may appear, are designed for their good and must be obeyed. By what means can we best lead people of this province to understand this first principle of all sanitary progress? Instruction of the young at schools and colleges will not be without its effect, but what is really needed more than anything is that the educated members of the community should bring home to the poorer classes the merits of practical hygiene. That has been well defined to aim at "rendering growth more perfect, decay less rapid, life more vigorous, death more remote." In season and out of season those who have learnt the lesson that without sanitation there can be no moral or material progress should preach to the public on the text that health means happiness. With stronger sinews the daily toil of a generation reared under more favourable conditions than those of the past will become more easy. So shall the earth be led more readily to bring forth her increase; here, we may surely hope, lies the

Margaret-street Hospital for Consumption and Diseases of the Chest, Cavendish-square, W.—Honorary Pathologist.

Middlesex Hospital.—Second Assistant to the Director of the Bacteriological and Clinical Laboratories. Salary £100 per annum. Also Hollins, Emden, and Salters Company's Scholarships. Value £100 per annum each.

Mount Vernon Hospital for Diseases of the Chest, Hampstead and Northwood, Middlesex.—Clinical Pathologist. Salary 100 guineas per annum.

Newport and Monmouthshire Hospital.—Third Resident Medical Officer. Salary £60 per annum, with board, residence, and laundry.

New South Wales, Australia, Queen Victoria Homes for Consumptives.—Resident Medical Officer, unmarried. Salary £250 per annum, with board and residence.

Oxford, Radcliffe Infirmary and County Hospital.—Junior House Surgeon, unmarried. Salary at rate of £40 per annum, with board, &c.

Papa Westray Parish Council, Orkney.—Public Vaccinator. Salary £90 per annum, with fees and house.

Pendlebury, Manchester Children's Hospital.—Visiting Physician. Honorarium £100 per annum.

Plymouth, South Devon and East Cornwall Hospital.—Surgeon.

Portsmouth, Royal Portsmouth Hospital.—Senior and Assistant House Surgeon, both for six months. Salary £100 and £50 per annum respectively, with board, &c.

Prince of Wales' General Hospital, Tottenham, N.—House Surgeon, House Physician, Junior House Surgeon, and Junior House Physician, all for six months. Salary of two former £75 per annum, and of two latter £40 per annum, with residence, board, and laundry. Also Honorary Anæsthetist.

Royal Ear Hospital, Soho.—House Surgeon. Salary £40 per annum.

Royal Navy, Medical Department.—Fifteen Commissions.

St. Bartholomew's Hospital.—Assistant Aural Surgeon.

Southend-on-Sea Education Committee.—School Medical Officer. Salary £250 per annum.

Staffordshire County Asylum, Cheddleton, Leek.—Junior Assistant Medical Officer for six months. Salary £150 per annum, with board, residence, laundry, &c.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Tiverton, Devonshire, Infirmary and Dispensary.—House Surgeon and Dispenser. Salary £80 per annum and all found.

Tottenham Education Committee.—Assistant Medical Officer. Salary £250 per annum.

Truro, Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Tunbridge Wells General Hospital.—Senior and Junior House Surgeons, unmarried. Salary, Senior £100, Junior £80 per annum, with board, apartments, &c.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry. Also Honorary Anæsthetist.

Virginia Water, Surrey, Holloway Sanatorium Hospital for the Insane.—Junior Assistant Medical Officer (female). Salary £150 per annum, rising to £200, with board, lodging, laundry, attendance, &c.

Westminster Hospital, Broad Sanctuary, S.W.—Fourth Assistant Physician.

Winchester, Royal Hampshire County Hospital.—House Physician, unmarried. Salary £65 per annum, with board, residence, &c.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Poole, in the county of Dorset.

Births, Marriages, and Deaths.

BIRTHS.

Cook.—On Sept. 27th, at Mengo, Uganda, East Africa, the wife of John Howard Cook, M.S., F.R.C.S., of a son.

Cooke.—On Oct. 4th, at 14, Arden-road, Church End, Finchley, N., the wife of E. Hunt Cooke, M.A., M.B., G.I.P.Ry., Lonavla, Bombay, of a son (Alfred Hunt).

Maingay.—On Oct. 4th, at Queen-street, Scarborough, the wife of H. B. Maingay, F.R.C.S., of a daughter.

Scott Turner.—On Oct. 4th, at Anerley-road, Upper Norwood, the wife of Arthur Scott Turner, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

Fell—Wallace.—On Sept. 30th, at Lindridge Church, Worcestershire Matthew Henry Gregson Fell, Captain R.A.M.C., to Marion Isobel, only child of the late Robert Wallace.

Scoones—Stanley-Adams.—On Sept. 30th, at St. Mary's Church, Spring-grove, Isleworth, Harold Edward Scoones, M.R.C.S. Eng., L.R.C.P. Lond., to Ethel Constance, third daughter of the late William S. Stanley-Adams, M.D., C.M., and Mrs. Stanley-Adams.

DEATHS.

Campbell.—On Oct. 2nd, at Villa Malibran, near Nice, Charles Moss Campbell, M.D. Edin., aged 64. Friends will please accept this the only intimation.

Leahy-Lynch.—At 2, Finsbury Park-road, London, N., on Oct. 5th, Tim Leahy-Lynch, M.D., in his 51st year. Beloved husband of Agnes Murdoch.

Leeson.—On Oct. 4th, at St. Leonards-on-Sea, Arthur Edmund Leeson, M.A., M.D., aged 76 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EXEMPLARY SENTENCES UPON GARBAGE-MONGERS.

We are able to record two more sentences which may serve as salutary deterrents upon persons who make a living by selling diseased or decomposed meat to the public. At Clerkenwell police court on Sept. 30th Alfred Wagner of Finsbury was fined £50, with an alternative of three months' imprisonment, for having a quantity of bad pork on his premises, upon which were appliances for making sausages, saveloys, and other highly flavoured foods in which the taste of bad meat can be disguised. An inspector found 20 pounds of scrap meat which was soft and smelt very offensively. Mouldy meat was in the ice-safe, and stinking pigs' heads were found which the defendant admitted that he had bought at 1s. per stone. Altogether 250 pounds of unsound meat were seized. The other case occurred at Newcastle on the same day, when William Dunn was charged with having in his possession a heifer for the purpose of preparation for sale, which was unfit for the food of man. It was stated that Dunn, in addition to carrying on business in the butcher market, carried on a shipping business, and that he kept two class of beasts, one for the "family trade" and one for the supply of ships. The animal in question, which was badly tuberculous, was intended for the latter purpose. It was alleged that similar small beasts, known as "stirks," were kept, on the premises until a shipping order came in, when they were slaughtered, dressed, and sent straight on board ship, and the inspector never got a chance of inspecting them. The defendant's manager admitted that the better class of beast was insured against tuberculosis but not the "stirk" class. The bench characterised the case as disgraceful and inflicted the maximum fine—£20 and costs, or three months' imprisonment. A second charge of a similar nature was admitted. In the course of the hearing it was given in evidence that three men do all the inspection in the 132 slaughter-houses of Newcastle and carry out the Diseases of Animals Act for the whole city as well, a staff which appears insufficient for adequate supervision.

SURGERY HOURS FOR POOR-LAW PATIENTS.

To the Editor of The Lancet.

Sir,—It has been customary in the six parishes of the union in which I am a district medical officer to have a morning hour for seeing parish patients. The guardians have now passed a resolution asking the medical officers to "set apart half an hour each evening for receiving parish patients." Hitherto a few patients have been seen in the evening, but this has been more or less voluntary. I should be glad to know from your readers if it is the usual custom through England for parish patients to have the choice of coming to the surgery either in the morning or evening.

I am, Sir, yours faithfully,

Sept. 30th, 1908. District Medical Officer.

A DISGUSTING PRACTICE.

At Swansea on Sept. 30th a milkman was fined £5 for not keeping his milk cans clean. It was proved that the man used his milk cans for holding and carrying "pigs' wash." For the defence it was contended that hot water would cleanse the cans and that "the practice had been carried on by hundreds of milkmen."

EARLY ENGLISH MEDICAL BOOKS.

To the Editor of The Lancet.

Sir,—I can assure Dr. Oscar Jennings that I did not think that he meant "work" when he said "book." As to the meaning of the term "book," it seems to me that as the British Museum has an officer entitled Keeper of the Printed Books the existence of a class of books which are not printed is implied, but the point is of very little importance. With regard to medical works of the fourteenth and fifteenth centuries being the earliest works in English, I purposely did not refer to the Leechbook of Bald and the other Anglo-Saxon medical manuscripts which were edited by Cockayne, for although Anglo-Saxon was the language spoken in England in the tenth century it can hardly, I think, be called English. Take, for instance, the following sentence, though I have taken it from the Anglo-Saxon Life of St. Guthlac, which MS. may be of earlier date than the Leechbook, as I have no copy of the latter work at hand: "Ne he caihtlice galnysse næs begangende, ne idele spellunge folcricra manna, ne ungeliclice olæcunge, ne leaslicetunge." By English I mean such a form of that language as an ordinary educated man could read with a fair amount of facility nowadays.

I am, Sir, yours faithfully,

Oct. 6th, 1908. M.D.

THE "IDEAL VALVE" FEEDER.

We have received from Messrs. H. and T. Kirby and Co., Limited, 14, Newman-street, London, W., a feeding-bottle for infants which is of the familiar boat shape. The points claimed in its favour are that it is open at both ends and so can be flushed under a stream of water; that it has no corners, and therefore can be thoroughly cleansed; and that it is graduated, as a guide to the quantity of the food given. It is also fitted with a solid lived 15 hours. *One was born by induction of labour* at eight months. The child was stillborn.

It will be noticed that in three cases labour was artificially induced, and of the children two out of the three were saved and are alive now, April, 1908, whereas in the three cases where labour came on prematurely of itself two out of the three children were lost.

As regards symphysiotomy and Cæsarean section in this case, both operations were performed only after failure to effect delivery of a living child by the forceps. It may be asked why symphysiotomy was not performed on the second occasion instead of Cæsarean section. One reason was that there were grounds for believing that the pubic bones after the symphysiotomy were united partly by bony union. The other chief reason was that I much prefer Cæsarean section to symphysiotomy. I believe the former to be little, if at all, more dangerous, while the convalescence after it is so much more rapid and satisfactory. From the point of view of the child it runs little or no risk in Cæsarean section but a very definite risk in symphysiotomy. The success of the latter as regards the child depends largely on a very accurate estimation of the pelvic measurements and also of the size of the child's head. While the pelvis may generally be measured with approximate accuracy the size of the child's head in relation to it must be more or less an uncertain factor. For my part, I agree with Whitridge Williams in feeling very little inclination to perform symphysiotomy rather than Cæsarean section in future.

Upper Brook-street, W.

SOME POINTS ABOUT PUNCTURE OF THE BRAIN.

BY PROFESSOR H. TILLMANNS, M.D.

PUNCTURE of the brain, like trephining, is a very old operation and was practised at the time of Hippocrates. In recent times particular attention has been paid to this operation by Middeldorpf, Souchon, Schmidt, Kocher, Payr, and more especially by Neisser and Pollack. Neisser and Pollack[1] have written a long treatise on the subject. They cite 36 cases in which puncture of the brain was performed 136 times. We certainly gather from their observations that in suitable cases excellent results may be obtained from puncture of the brain both from the diagnostic and from the therapeutic point of view. It is remarkable that puncture of the brain has not been more universally studied. We find little or no mention of the operation in the handbooks on internal medicine or on neuropathology. As in the case of lumbar puncture, puncture of the brain will certainly come to be more universally practised, both for the purpose of diagnosis and also for treatment of diseases of the brain.

A *diagnostic*, that is an exploratory, puncture is indicated in all cases where the diagnosis is uncertain. Where injury or disease of the cranial cavity or of the brain is evident, the typical trephining operation will of course be performed. A diagnostic puncture is indicated when there are signs of pressure on the brain or when an accumulation of blood, pus, or other fluid is suspected either in the cranial cavity, in the brain itself, or in the ventricles of the brain; also in the cases of cysts, tumours, foreign bodies, &c. In certain cases the diagnostic puncture must be immediately followed by the definite operation—that is, trephining and removing the cause of the disease. Neisser and Pollack in particular have shown that even in advanced cases of pressure on the brain—for instance, in cases of intracranial hæmorrhage, extravasation, cysts, &c.—puncture can give excellent results and bring about cures which could hardly be expected.

Therapeutical puncture has been principally practised in cases of hydrocephalus, dropsy of the ventricles (in some cases with subsequent drainage), and also for the purpose of making injections—for instance, of tetanus antitoxin in cases of tetanus—into the cranial cavity, into the brain itself, or into the lateral ventricles. This intracranial injection of tetanus antitoxin has rightly been abandoned in favour of subcutaneous injections, into the veins, or better into the spinal cord, and of endoneural injections, particularly into the larger nerves which must previously be laid bare. For instance, in the case of wounds to the hand where tetanus is suspected, I recommend, as do Anschütz and others, an immediate prophylactic injection of tetanus antitoxin into the exposed brachial plexus, as tetanus poison, according to the experiments of Hans Meyer and Ransom, only reaches the central nervous organs through the axis cylinders of the motor nerves. This endoneural injection of tetanus antitoxin is particularly efficacious; when made prophylactically, before the appearance of the actual tetanus symptoms.

The technique of aseptic puncture of the brain is as follows. The preliminaries are the same as for trephining: shaving of the particular part of the scalp, in some cases of the whole head, and thorough cleansing of the same with soap, spirits of soap, ether, benzene, or alcohol. We generally employ local anæsthesia with cocaine-adrenalin or novocaine-adrenalin or, if necessary, general anæsthesia. The spot where the operation is to be performed can be fixed, if necessary, with a craniometer. The point is found partly by studying the existing symptoms—for example, of the probable seat of a tumour, of an accumulation of blood or matter, of a cyst, &c. In other cases the spot is arbitrarily fixed when it is decided to puncture the ventricle. Occasionally general circumstances have to serve as a guide to the point where the puncture is to be made. A lesion of the larger blood-vessels and of the cerebral sinuses must, of course, always be avoided. When the spot has been selected either a small incision is made down to the bone and the periosteum is pushed aside, or else section of the pericranium is avoided altogether. In the latter case a hand or electric brace, fitted with a round-headed Doyen or Sudeck drill, is pressed firmly on to the skin, which is pierced at the same time as the bone below. When drilling through the bone it is advisable to press more firmly at first than later in order to avoid injuring the dura mater after piercing the inner table. Injury of the dura mater is best avoided by first using a broad-pointed, oval-shaped Doyen drill to pierce the cranium, and then using a ball-pointed Doyen drill to pierce the inner table. With this drill an injury to the dura mater is impossible. Payr recommends using a drill fitted with a guard against cutting too deep. Hæmorrhage of the bone can be stopped by spreading on aseptic wax. When the cranium has been pierced a fine hollow needle fitted to a Pravaz syringe that closes well is inserted and suction is produced. This suction must be performed as delicately as possible so as to avoid causing hæmorrhage. The fluid matter which is abstracted should, if necessary, be examined at once microscopically and bacteriologically. Should the puncture produce no result, or should it be impossible to elucidate the case sufficiently through the small aperture in the bone, the opening can be enlarged as required either with a larger ball-pointed Doyen drill or with a Dahlgren forceps in order, for instance, to judge the pulsation of the brain, intracranial pressure, &c. When a larger opening has been made the dura mater should be taken hold of with a small-pointed hook and cut crosswise with a very sharp thin knife. The suspected hæmorrhage, abscess, or cyst is then pierced with a fine hollow needle or a thicker one; grooved needles or a very fine sharp knife can also be used. In cases of tumour this simple aseptic piercing of the cranium with the ball-pointed Doyen drill is also devoid of danger, and Neisser and Pollack have shown that with the above-mentioned simple puncture the presence of a tumour can be discovered—for instance, in the frontal lobe of the brain—where it had not been expected and where it would have been impossible to ascertain its existence in any other way. If necessary the puncture can be repeated, as the operation is relatively simple. Neisser once punctured nine times in succession and finally succeeded in locating the suspected tumour. In the cases of newly born children and of hydrocephalus it is usually not necessary to pierce the bone. The cranium is opened at a suitable membranous spot where there is neither a large blood-vessel nor a cerebral centre—for instance, next to the sinus longitudinalis.

Various points of the cranium have been recommended for the puncture of the lateral ventricle. This operation is especially indicated when there is an accumulation of liquid in the same, particularly in cases of hydrocephalus internus. In certain cases the puncture is combined with a subsequent drainage of the ventricle. The motor area, the neighbourhood of the fissure of Sylvius, and the known centres of

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. *It is urgently necessary* that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Leeds Mercury, Hanley Sentinel, Dundee Advertiser, Bradford Telegraph, Morning Leader, Leeds Post, Leeds Evening Post, Manchester Guardian, Glasgow News, Pall Mall Gazette, Carlisle Express, Sheffield Telegraph, Westminster Gazette, Wolverhampton Express, Downpatrick Recorder, Yorkshire Observer, Scotsman, Manchester News, Birmingham Post, York Herald, Dublin Times, Exeter Gazette, Belfast News Letter, Wolverhampton Evening News, Cardiff News, &c.*

Some patients described the malaise as of the nature of sea-sickness, but there is a total absence of uniformity in the symptomatology and such symptoms as presented themselves occurred separately and in very variable degree. Vomiting was noted in 22 per cent. of the cases. In 7 per cent. of these there was sweating and in 14·7 per cent. nausea. As a general rule the vomiting did not last more than five minutes and but very rarely has it recurred later in the day or on the following day. Since 1905 I have succeeded in reducing the frequency of nausea and vomiting by 50 per cent. by giving the patients their breakfast before making the injection. On several occasions the nausea, &c., subsided on the administration of a liqueur glassful of Chartreuse. Vomiting is admittedly a disagreeable incident but we are equally exposed thereto when we use chloroform and ether. Epileptoid tremor of the lower limbs was noted in three cases but in no instance was it severe enough to prevent my going on with the operation.

Fatal syncope is one of the gravest accidents urged against the method, especially since the cases of Legueu, Broca, and Dumont. I am pleased to report that nothing of the kind has occurred in my practice for I cannot admit as imputable to the method the case recorded in my pupil, Genova's, thesis. The subject was a man, 31 years of age, who was sent to be operated on at once for pyo-pneumonia. As a matter of fact he was almost moribund. The temperature was 41° C., the pulse was 130, with marked and repeated rigors. The injection was made at 10.40 and the pulse soon after was 132. While engaged in sterilising my hands the patient, not being able to breathe lying down, struggled into a sitting position, whereupon he was seized with intense dyspnœa and soon died. Post mortem we found an enormous purulent effusion into the pleural cavity, with a large quantity of fluid in the pericardium and bilateral nephritis. Death followed the injection almost at once so that if it were due to the cocaine the latter would have to be assumed to be capable of instantaneous action which is not in accord with my experience; indeed, I felt so strongly that death was in no wise imputable to the cocaine that I went on employing the method as in the past.

Like chloroform, ether, methyl chloride, &c., cocaine has its contra-indications which must be borne in mind. Advanced cachexia, bilateral nephritis with scanty urinary secretion, myocarditis, pericarditis with effusion, and non-compensated cardiac affections are pathological conditions that absolutely prohibit the use of cocaine. This the surgeon must bear in mind lest he run the risk of grave disaster which would tend to bring a very useful method into disrepute.

Later disturbances.—The only two untoward consequences at a later period have been headache and rachialgia. The headache comes on either on the day of the operation, possibly with slight rise of temperature, or on the day following. It was noted in 9·36 of the cases. In one case, that of a hysterical woman, it lasted three days and resisted all treatment. The incidence of the headache, moreover, is very variable: it was 18 per cent. among the male patients and 19 per cent. among the female patients during the period 1901–02. Between July, 1902, and July, 1903, the proportion was only 6 and 1·8 per cent. respectively, while since 1903 it has been 2 per cent. in men and 0 per cent. in women. These differences may be explained by the fact that in the early times it was my practice to allow the escape of a quantity of cerebro-spinal fluid roughly equal to the amount of fluid to be injected. In view of the relief to the headache in meningitis afforded by the evacuation of 40 or 50 grammes of cerebro-spinal fluid I made up my mind to evacuate more freely and instead of making the injection as soon as the needle was introduced it has been my habit to let the fluid trickle away while I slowly filled the syringe, taking the greatest care to expel every trace of air from the fluid to be injected. At the beginning no note was taken of the amount of cerebro-spinal fluid allowed to escape but later it was measured and we found that when the pressure was small some 10 or 12 grammes came away, whereas if high we obtained from 15 to 20 grammes. I may add that it sometimes happened that the temperature rose in the afternoon to 38° or 39° C. with accompanying headache but this was never severe enough to prevent the patients going to sleep. Patients who are prone to migraine seem to be more subject than others to post-operative headache, and in these subjects the headache follows the injection of stovaine just as frequently as with cocaine. I have remarked that arthritic and alcoholic subjects, especially if suffering from arterio-sclerosis, are especially liable to headache after spinal anæsthesia. Rachialgia is alleged by some observers to be a sign of meningeal irritation but although a few patients complained of pain in the spine it never amounted to positive inconvenience.

Delayed troubles.—A great deal has been said and written about the ultimate effects of cocaine on the nerve centres but these allegations must be judged in the light of practical experience. Now it is some seven years since I began to employ spinal anæsthetisation and among the many hundreds of persons upon whom I have practised the method not a single instance of medullary mischief has been met with in such as have since been seen. As for the others, we may be sure that if anything of the kind had supervened we should infallibly have been informed of the fact either by the relatives or by the medical man.

I therefore feel justified in asserting on the strength of a somewhat extensive experience that spinal anæsthesia by means of cocaine is practically devoid of danger, provided, of course, that asepsis be perfect. The same precautions must be taken as for a laparotomy, for the danger lies not in the introduction of therapeutical doses of cocaine into the spinal canal but in the possibility of affording entrance to pathogenic organisms. In my opinion all accidents that occur are to be ascribed to a defective technique and not to the method *per se.*

I do not pretend that the method is free from drawbacks of any kind. There is the headache, for instance, but although in certain cases it was decidedly troublesome it has never been "awful," and I have shown what can be done to reduce this symptom to a minimum. Admitting the reality of this drawback, can it be allowed to weigh against the unquestionable advantages of the method? One has only to compare the appearance of the patient who has been anæsthetised by spinal cocainisation and that of one who has been rendered insensible by the aid of chloroform or ether. The former is calm, smiling, self-possessed enough to express his surprise at the novel experience and to thank the surgeon for his care and attention; then, too, he is able to take food before and immediately after the operation, while the other is absolutely prostrate, is still sleeping, or is awake and vomiting. In the latter, too, there is more or less pronounced operative shock which is conspicuous by its absence in the former.

The method is invaluable for the country medical man who is so often obliged to act both as anæsthetist and operator, for he has nothing to fear so far as the anæsthesia is concerned, and he is not exposed to the risk of a scare. Then, too, many patients have an invincible objection to being "sent to sleep," and in these spinal anæsthesia is the ideal alternative. On the other hand, I strongly disadvise recourse to this method for persons who object to it. For the indifferents who care not what plan is adopted it is easy to prevent their knowing what is going on. The eyes should be covered with a light bandage and absolute silence should be maintained. The only real drawback that I recognise in respect of this method—and it is a very awkward one for the surgeon—is that in certain nervous and alcoholic subjects the anæsthesia is not complete. This difficulty, after all, can be overcome by giving chloroform or ether, which in this event act much more readily and in much smaller doses.

Conclusions.—1. Spinal cocainisation is absolutely free from danger. 2. Spinal cocainisation, by Tuffier's method, may be employed from 10 or 15 years of age up to extreme old age for all operations on parts below a line running horizontally across two fingers' breadth below the breasts, or we may take the eighth rib as the limit. 3. The drawbacks alleged against the method can be minimised by attention to the points referred to to such an extent as to render them quite negligible in view of the advantages—viz., absolute safety, suppression of operative shock, &c. 4. It is an excellent mode of inducing anæsthesia which has been unjustifiably decried and deserves to be practised under suitable conditions. 5. My experience with stovaine is not sufficient to enable me to formulate a definite opinion, but it is my intention in future to employ stovaine instead of cocaine in order to arrive at a trustworthy conclusion as to their respective merits.

SPINAL STOVAINISATION.

So far I have employed stovaine in 108 cases in patients between 18 and 71 years of age in doses of from 5 to 10

The Harveian Oration

ON

HEREDITY IN RELATION TO DISEASE.

Delivered before the Royal College of Physicians of London on Oct. 19th, 1908,

BY J. A. ORMEROD, M.D. OXON., F.R.C.P. LOND.,

ASSISTANT REGISTRAR TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, LONDON.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN,—My first duty is to thank you, which I do most sincerely, for intrusting to me the very honourable, though very arduous, duty of delivering the Harveian oration this year. Such an honour must bring to the mind of any man—it certainly did to mine—first a feeling of pleasure and of pride, which I hope may be pardoned, and next a feeling of much anxiety and misgiving as to one's qualification for the task. For it is indeed a serious thought that ever since 1656, with but few intervals, this oration has been delivered by a long line of distinguished physicians who have vied with one another in holding up to admiration the life and work of the illustrious man whom we commemorate to-day. Certainly, had it been possible I should have wished to bring before you fresh facts about Harvey or to present some fresh aspect of his genius or his character. But that I cannot hope to do. For have we not already excellent lives of Harvey, two of them, at least, recently written, the work of skilful and sympathetic historians like Dr. Norman Moore and Mr. D'Arcy Power? And have not Harveian orators within our recollection elucidated fully the leading points and bearings of Harvey's work? Dr. George Johnson vindicated the originality of his great discovery; Sir Edward Sieveking brought before the College his rediscovered Lumleian lecture notes; Sir William Church has traced, from Harvey as its source, the rise of physiology in England; Dr. J. F. Payne has shown us the influence of Galen upon Harvey; Dr. Norman Moore and Professor William Osler have drawn for us brilliant word pictures of the man, his times, his friends, and his lectures at this College. Alas, that I cannot compete with them! that I have no fresh offering to lay on Harvey's shrine! and that I can only bow my head, as do we all, in memory of this great and good man, of his noble character, his transcendent genius, and his immortal discoveries.

But there are certain definite wishes expressed by Harvey about this oration. One is that there be "an exhortation to the Fellows and Members to search and study out the secrets of Nature by way of experiment." Now as to experiment in the limited sense of physiological experiment, may we not say that this wish has attained its consummation? No reasonable medical man, certainly no Fellow or Member of our College, would deny the greatness of the debt which medicine owes to experimental science. How far would the science and art of medicine have progressed without a knowledge of the circulation?—a knowledge which was obtained, as Harvey himself tells us, by experiment, by the vivisection of many animals. The interdependence of modern medicine and experimental science was shown by your orator of last year, Dr. Frederick Taylor, so fully that I need not tread that ground again. It is true that we cannot all be experimentalists either in physiology or in other branches of science. But there is no need to place that narrow limit on Harvey's words. Certainly he speaks to each and all of us; but I think he means to emphasise here, as he so often does elsewhere, the importance of independent individual research, whether by experiment or observation, as opposed to a blind or lazy submission to current theory and authority. Knowledge of other men's opinions he certainly did not underrate, for he was himself a most learned man; but he refused to let learning trammel investigation, and would not look at Nature through the distorting medium of a theory. And this frame of mind is as valuable now as then, and necessary, above all things, in the study of medicine; for of many medical theories one is tempted to say—

> "Our little systems have their day:
> They have their day and cease to be."

Another wish of Harvey is that there should be "a commemoration of all the benefactors of the College by name, with an exhortation to others to imitate these benefactors." As a benefactor who has not yet been mentioned in a Harveian oration, I ask you to honour to-day Dr. Charles Coates, a senior Fellow of our College, who has given a sum of £1000 towards providing some hospitable entertainment for our Members and Licentiates. This idea, suggested as I believe, Sir, by yourself, took a tangible form in the successful conversazione of last summer. Such hospitality is entirely consonant with Harvey's spirit, and that entertainment of the Members and Licentiates was the proper complement of the "general feast" which he instituted for the Fellows to-day.

Now the names of those benefactors who have founded lectures, scholarships, and prizes are recorded with all due particulars in the Annual List of the College, and are so well known to you that I need not recapitulate them. But besides these, and others than these, who have given money, lands, books, or other good things to the College, there are those who have devoted their time and talents to its service, or who have shed a lustre upon it by their learning, their discoveries, or their distinguished career. They also, in the truest sense, are benefactors of the College. I look in that invaluable book, Dr. Munk's "Roll of the College of Physicians," and I see first a long list of Presidents under whose care and devotion the College has thriven, reaching back from yourself, Sir, to our revered founder Linacre; next, men famous in science, physicists like Gilbert, Wollaston, Thomas Young, Arnott; chemists such as Prout and Alexander Marcet; naturalists and botanists such as Fothergill, William Pitcairn, Sir Hans Sloane; anatomists and physiologists, at whose head stands Harvey himself, Richard Lower, and such great names as those of Glisson, Havers, William Hunter, Wharton, Willis. There have been famous authors and men of letters—Sir Thomas Browne, the anniversary of whose birth and death is to day, Akenside, Arbuthnot, Garth, and (strange constrast) Stukeley the antiquarian, and many others well known for scholarship, learning, and literary talent. There are the great masters and discoverers in medicine, such as Sydenham, Matthew Baillie, Bright, Addison. And some have been also known for their simplicity of character, their high ideals, and their life of transparent goodness. Such, I think, must have been David Pitcairn, of whom Dr. Munk says that he was simple, gentle, dignified, and very kind of heart; and such William Babington, of whom the same authority says: "History does not supply us with a physician more loved or more respected"; and such an one was Peter Mere Latham—scholar, physician, inspiring teacher, eloquent writer, high-toned gentleman, devout Christian. I know that one of our Fellows, whose untimely death we all deplore, took Dr. Latham, though he never saw him, for his model and example.

These are but a few of the many noble figures which fill the great pageant of our past. But need I, Sir, say more? for I am sure that Fellows of the College know so well the lives and works of our illustrious predecessors that for an "exhortation to imitate them" it will suffice to have recalled their names.

Many of my predecessors in this office have varied the theme of their Harveian oration by introducing into it some subject of general medical interest, and I ask your leave, Mr. President, to follow their example. I desire to direct attention to the great subject of heredity, and in particular heredity in relation to disease. A distinguished German physician has said "There are no inherited diseases." We need not argue that, for we should all admit that heredity has much to do with the production of disease. Now of that mysterious thing inheritance I need only say that it lies at the very root of our being both as individuals and as a race, as indeed is recognised in the proverbs and the religions of all nations. "Fortes creantur fortibus," said Horace. "The fathers have eaten sour grapes and the children's teeth are set on edge." The Chinese worship their ancestors, and there are words familiar to ourselves concerning a visitation "unto the third and fourth generation."

This year, too (1908), is the fiftieth anniversary of the paper instruments for tracheotomy and several large catheters. Upon arrival I found the patient propped up in a sitting posture in bed. Her face was dusky and there were greatly increased stridor and dyspnœa with intercostal recession during inspiration and she was losing consciousness. I injected five minims of solution of strychnine, opened the mouth and separated the teeth with a gag, and guiding with a finger passed a No. 10 catheter (with the eye cut off) down the trachea several inches. This was immediately followed by respiratory relief and return of consciousness and loss of duskiness. The temperature was subnormal and the pulse very slow and was hardly felt. I again injected five minims of solution of strychnine, applied hot fomentations and mustard poultice to the præcordia, and sent for my partner. After a short time the catheter became blocked with mucus and respiration became embarrassed; it was necessary to remove the catheter and to replace it with a larger one, a No. 12; in the short time taken the patient became unconscious and the respiration ceased. The lungs were inflated by blowing down the catheter, when the respiration recommenced as well as partial return of consciousness. By this time my partner had arrived and we decided that tracheotomy should be performed at once, the high operation, and a tube passed down beyond the obstruction, as owing to the turgid state of the vessels of the neck it would be very risky to attempt the division of the isthmus until after respiration was restored. The father and relatives, however, could not possibly be persuaded to allow anything in the way of an operation, notwithstanding the desperate urgency of the case, although several attempts were made to induce them. The patient was again showing signs of increased difficulty in breathing on account of the accumulation of mucus in the catheter, and becoming much worse strychnine was again injected and artificial respiration was resorted to. The father was once more appealed to and after some delay his consent was given to operate.

The patient was now quite unconscious. I immediately performed tracheotomy, quickly removed the catheter from the mouth, and inserted a tracheotomy tube in the trachea, passing through it a No. 14 catheter. The patient had now ceased to breathe and the lungs were inflated several times by blowing down the catheter and artificial respiration was continued for some time, but unfortunately without any response; the heart now ceased beating. After some little time the tube was removed and the wound and trachea were carefully examined; the obstruction was situated opposite and below the isthmus. There was no sign of diphtheritic membrane.

In this sad case two things might well be considered. First, did the iodide of potassium and the syrup of iodide of iron cause contraction of the gland so as to increase the pressure upon the trachea and increase the irritation of the recurrent laryngeal nerve? I hardly think so as I have successfully treated several other cases of simple goitre in the same manner, as it is very common in this part of Sussex. Secondly, the fact that the heart was still to be heard beating, although very slowly (the pulse at the wrist was imperceptible), led me to hope that there might have been some response after the tube was inserted and the lungs inflated and artificial respiration resorted to for some time. But the gradually progressing slowness of the pulse noted from the first appears to point to cardio-inhibitory action being the real cause of death, which might have been relieved by division of the isthmus in time, and perhaps should have been done at once, after the tube had been introduced. Most unfortunately, the patient was practically moribund before permission to operate was obtained.

As these cases are rare and there is very little literature on the subject it would be instructive to hear the experience of others.

Cowfold, Sussex.

HOSPITAL SUNDAY AT EXETER.—Oct. 18th, St. Luke's Day, was celebrated as Hospital Sunday at Exeter Cathedral, when collections were made for the Royal Devon and Exeter Hospital. The committee, staff, and governors of that institution met the mayor and other representatives of civic bodies at the Guildhall and walked in procession to the cathedral to attend the afternoon service.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Malformation of the Urethra in the Fœtus as a Cause of Dystocia.—Uterine Fibroid showing Peritheliomatous Changes.

A MEETING of this section was held on Oct. 8th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. JOHN EVAN SPICER read a paper on Malformation of the Urethra in the Fœtus as a Cause of Dystocia, with some considerations on secretion of urine in the fœtus. Photographs and drawings of a six months' fœtus delivered by Dr. Spicer were shown and the clinical history was given. This fœtus was found to have imperforate urethra and enormous dilatation and hypertrophy of the bladder. Diagnosis and treatment of such cases were reviewed in the light of about 70 other cases collected from the literature of the last 100 years. After a short summary of an exhaustive dissection of the fœtus Dr. Spicer proceeded to discuss the results of imperforate urethra in the fœtus and said that in itself the atresia in no way interfered with the general growth in utero, nor did it of necessity create other complications in utero which rendered the life of the newly born infant impossible. It became dangerous in utero only in the presence of a large secretion of fluid by the fœtal kidney, and such secretion he believed to be pathological. The fœtal kidney normally allowed the filtration of a small quantity of watery fluid but the amount was insignificant. The kidney was not employed as an excretory organ in utero unless a breakdown occurred—partial or complete—in the normal mechanism, by which the mother performed the whole of the excretory function of her child. That mechanism depended on the integrity of the combined circulation and was amply provided for through the placenta. A physiological breakdown might be said to occur with the onset of labour, beginning perhaps some little time previously, so that children were often born with urine in the bladder. The kidney, like the other major organs, though capable of carrying on post-natal functions of a sort at an earlier date than the tenth lunar month if necessity demanded, remained in abeyance during fœtal life. The effect of accumulation of fluid in the fœtal bladder depended on the amount, the rate, and the date of secretion, and especially on the possibility of evacuation. Hypertrophy and dilatation of the bladder wall could only arise where there was an actual or virtual means of exit for the contained fluid.—The PRESIDENT said that without further consideration he did not feel inclined to give up the view which he had long held, that the fœtus normally secreted urine and passed it into the liquor amnii during pregnancy. He had met with at least half-a-dozen cases of stenosis of the ureters in stillborn children in which the ureters were distended with urine above the obstruction; in one case the distended ureter gave rise to dystocia. When the kidneys were absent the liquor amnii had been observed to be very scanty. With regard to the statement that the fœtal secretions remained in abeyance till birth, it was certainly not true of the vaginal or uterine secretions, for he had found the vagina and body of the uterus greatly distended when the outflow of mucus was obstructed by stenosis or by tumours.—Mr. ALBAN H. G. DORAN observed that quite recently a case of oligohydramnion had been reported where both kidneys were absent in the fœtus and the bladder was empty. The suprarenal bodies were hypertrophied. The absence of the kidneys was held to support the theory that the liquor amnii was mainly supplied by the fœtus but Mr. Doran doubted if Dr. Spicer or any other competent obstetrician would be convinced on the evidence of a single case.—Dr. W. S. A. GRIFFITH said that the records of these cases showed that imperforate urethra was not necessarily followed by distension of the fœtal bladder and he was prepared to accept Dr. Spicer's view that interference with the normal secretory apparatus of the fœtus through the placenta was the cause of renal activity before birth and that this activity during intra-uterine life was therefore pathological. The class of cases which he believed Dr. Spicer had not referred to in his paper was that of

The Harveian Oration

ON

HEREDITY IN RELATION TO DISEASE.

Delivered before the Royal College of Physicians of London on Oct. 19th, 1908,

By J. A. ORMEROD, M.D. Oxon., F.R.C.P. Lond.,

ASSISTANT REGISTRAR TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, LONDON.

Mr. President, Fellows of the College, and Gentlemen,—My first duty is to thank you, which I do most sincerely, for intrusting to me the very honourable, though very arduous, duty of delivering the Harveian oration this year. Such an honour must bring to the mind of any man—it certainly did to mine—first a feeling of pleasure and of pride, which I hope may be pardoned, and next a feeling of much anxiety and misgiving as to one's qualification for the task. For it is indeed a serious thought that ever since 1656, with but few intervals, this oration has been delivered by a long line of distinguished physicians who have vied with one another in holding up to admiration the life and work of the illustrious man whom we commemorate to-day. Certainly, had it been possible I should have wished to bring before you fresh facts about Harvey or to present some fresh aspect of his genius or his character. But that I cannot hope to do. For have we not already excellent lives of Harvey, two of them, at least, recently written, the work of skilful and sympathetic historians like Dr. Norman Moore and Mr. D'Arcy Power? And have not Harveian orators within our recollection elucidated fully the leading points and bearings of Harvey's work? Dr. George Johnson vindicated the originality of his great discovery; Sir Edward Sieveking brought before the College his rediscovered Lumleian lecture notes; Sir William Church has traced, from Harvey as its source, the rise of physiology in England; Dr. J. F. Payne has shown us the influence of Galen upon Harvey; Dr. Norman Moore and Professor William Osler have drawn for us brilliant word pictures of the man, his times, his friends, and his lectures at this College. Alas, that I cannot compete with them! that I have no fresh offering to lay on Harvey's shrine! and that I can only bow my head, as do we all, in memory of this great and good man, of his noble character, his transcendent genius, and his immortal discoveries.

But there are certain definite wishes expressed by Harvey about this oration. One is that there be "an exhortation to the Fellows and Members to search and study out the secrets of Nature by way of experiment." Now as to experiment in the limited sense of physiological experiment, may we not say that this wish has attained its consummation? No reasonable medical man, certainly no Fellow or Member of our College, would deny the greatness of the debt which medicine owes to experimental science. How far would the science and art of medicine have progressed without a knowledge of the circulation?—a knowledge which was obtained, as Harvey himself tells us, by experiment, by the vivisection of many animals. The interdependence of modern medicine and experimental science was shown by your orator of last year, Dr. Frederick Taylor, so fully that I need not tread that ground again. It is true that we cannot all be experimentalists either in physiology or in other branches of science. But there is no need to place that narrow limit on Harvey's words. Certainly he speaks to each and all of us; but I think he means to emphasise here, as he so often does elsewhere, the importance of independent individual research, whether by experiment or observation, as opposed to a blind or lazy submission to current theory and authority. Knowledge of other men's opinions he certainly did not underrate, for he was himself a most learned man; but he refused to let learning trammel investigation, and would not look at Nature through the distorting medium of a theory. And this frame of mind is as valuable now as then, and necessary, above all things, in the study of medicine; for of many medical theories one is tempted to say—

> "Our little systems have their day;
> They have their day and cease to be."

Another wish of Harvey is that there should be "a commemoration of all the benefactors of the College by name, with an exhortation to others to imitate these benefactors." As a benefactor who has not yet been mentioned in a Harveian oration, I ask you to honour to-day Dr. Charles Coates, a senior Fellow of our College, who has given a sum of £1000 towards providing some hospitable entertainment for our Members and Licentiates. This idea, suggested as I believe, Sir, by yourself, took a tangible form in the successful conversazione of last summer. Such hospitality is entirely consonant with Harvey's spirit, and that entertainment of the Members and Licentiates was the proper complement of the "general feast" which he instituted for the Fellows to-day.

Now the names of those benefactors who have founded lectures, scholarships, and prizes are recorded with all due particulars in the Annual List of the College, and are so well known to you that I need not recapitulate them. But besides these, and others than these, who have given money, lands, books, or other good things to the College, there are those who have devoted their time and talents to its service, or who have shed a lustre upon it by their learning, their discoveries, or their distinguished career. They also, in the truest sense, are benefactors of the College. I look in that invaluable book, Dr. Munk's "Roll of the College of Physicians," and I see first a long list of Presidents under whose care and devotion the College has thriven, reaching back from yourself, Sir, to our revered founder Linacre; next, men famous in science, physicists like Gilbert, Wollaston, Thomas Young, Arnott; chemists such as Prout and Alexander Marcet; naturalists and botanists such as Fothergill, William Pitcairn, Sir Hans Sloane; anatomists and physiologists, at whose head stands Harvey himself, Richard Lower, and such great names as those of Glisson, Havers, William Hunter, Wharton, Willis. There have been famous authors and men of letters—Sir Thomas Browne, the anniversary of whose birth and death is to day, Akenside, Arbuthnot, Garth, and (strange constrast) Stukeley the antiquarian, and many others well known for scholarship, learning, and literary talent. There are the great masters and discoverers in medicine, such as Sydenham, Matthew Baillie, Bright, Addison. And some have been also known for their simplicity of character, their high ideals, and their life of transparent goodness. Such, I think, must have been David Pitcairn, of whom Dr. Munk says that he was simple, gentle, dignified, and very kind of heart; and such William Babington, of whom the same authority says: "History does not supply us with a physician more loved or more respected"; and such an one was Peter Mere Latham—scholar, physician, inspiring teacher, eloquent writer, high-toned gentleman, devout Christian. I know that one of our Fellows, whose untimely death we all deplore, took Dr. Latham, though he never saw him, for his model and example.

These are but a few of the many noble figures which fill the great pageant of our past. But need I, Sir, say more? for I am sure that Fellows of the College know so well the lives and works of our illustrious predecessors that for an "exhortation to imitate them" it will suffice to have recalled their names.

Many of my predecessors in this office have varied the theme of their Harveian oration by introducing into it some subject of general medical interest, and I ask your leave, Mr. President, to follow their example. I desire to direct attention to the great subject of heredity, and in particular heredity in relation to disease. A distinguished German physician has said "There are no inherited diseases." We need not argue that, for we should all admit that heredity has much to do with the production of disease. Now of that mysterious thing inheritance I need only say that it lies at the very root of our being both as individuals and as a race, as indeed is recognised in the proverbs and the religions of all nations. "Fortes creantur fortibus," said Horace. "The fathers have eaten sour grapes and the children's teeth are set on edge." The Chinese worship their ancestors, and there are words familiar to ourselves concerning a visitation "unto the third and fourth generation."

This year, too (1908), is the fiftieth anniversary of the paper practically normal. One section showed the head very beautifully and this, with others, was submitted to Mr. A. E. Shipley who thought that the parasite was the larva of either the blow-fly or of sarcophaga carnaria or sarcophaga magnifica. The ova of the blow-fly, or the larvæ of sarcophagidæ, were sometimes deposited in the nasal passages and other channels leading outward in man, and also on the conjunctiva in purulent cases. It was suggested that the larva might work its way from the conjunctival sac directly through the thin sclerotic of a child into the interior of the eye, or if deposited in the nostril might find its way by the nasal duct to the lacrymal artery and thence into the eye by way of the central retinal artery, or of one of the ciliary arteries. The possibility of this larva being that of hypoderma boris, of which there were two recorded cases in man and one in the horse, must not be overlooked, since the larva of this fly was of necessity parasitic in mammalia.—A discussion followed.

Mr. N. BISHOP HARMAN read a paper entitled "Six Generations of Piebalds." He showed a chart of the pedigree of a family in which there was a striking and continuous inheritance of certain skin and hair markings. Some of the members of the family were shown at the meeting. The features were: a white forelock, a white patch of skin spreading from beneath this lock of white hair down the centre of the forehead, and in some cases patches of white skin about the trunk or legs. The white tissues were appreciably more delicate than the normal skin and hair. The colour of the ordinary hair ranged from a light brown to a deep brown, almost black. There were no other abnormalities. The connexions of this family had been ascertained for six generations: of these, four were living. The generations comprised 34 childships and 138 individuals. Of the childships, nine showed the inheritance in direct descent. Mr. Harman considered the anomaly to be in the nature of a partial albinism. He discussed the nature of this family history in relation to the inheritance of disease by one or other sex and to the law of inheritance as propounded by Mendel.

Cases and specimens were shown by Dr. A. MAITLAND RAMSAY, Mr. SYDNEY STEPHENSON, Mr. J. B. LAWFORD, Dr. A. OGILVY, Mr. A. C. HUDSON, and Mr. C. WRAY.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Cerebro-spinal Meningitis in the Northern Territories of the Gold Coast.

A MEETING of this society was held on Oct. 16th, Sir PATRICK MANSON, *the President, being in the chair.*

Dr. A. E. HORN read a paper on an Investigation of Cerebro-spinal Meningitis in the Northern Territories of the Gold Coast. He said that serious outbreaks of cerebro-spinal meningitis had occurred in West Africa at intervals during the last 50 years. After giving the history of the present epidemic, which started about the end of October, 1907, Dr. Horn pointed out that the bacteriological characteristics agreed almost entirely with the main characteristics of Weichselbaum's diplococcus intracellularis meningitidis, otherwise known as micrococcus meningitidis cerebro-spinalis, or more shortly as the meningococcus, which had been shown to be the cause of the recent epidemics in Ireland, Scotland, and the continent, and to be the cause of epidemic cerebro-spinal meningitis in West Africa. There were other properties of the meningococcus of Weichselbaum which were of minor importance to the bacteriologist but of great importance in dealing with the disease which it produced; for instance, its vitality, its power of resisting desiccation, its pathogenicity on animals, its power of agglutinating with the serum of persons suffering from cerebro-spinal meningitis, its resistance to disinfectants, its methods of transference from one person to another, its power of producing immunity—all of which had been, and were still being, investigated but about which there was still considerable doubt. Experiments tended to show that the vitality of the meningococcus was not great; that it was easily destroyed by a comparatively low temperature and by desiccation, as cultures spread on cloth and dried at the ordinary temperature in daylight (not in direct sunlight) for 24 hours failed to survive. It had been practically proved by investigators in the epidemics of Europe that the meningococcus lived and was transported in the mucus of the naso-pharynx of "contacts," or persons who had been in close association with the disease, and the germ had occasionally been recovered from such sites. In regard to treatment, Dr. Horn said that the use of drugs was practically confined to the alleviation of symptoms, and he could not discover that any drug had any effect on the course of the disease. An early calomel purge and a counter-irritation in the form of liquor iodi or liquor epispasticus over the cervical spine gave some relief to the headache; cardiac tonics and stimulants were advisable early, and phenacetin and caffeine were of some temporary use if the temperature was unduly high. Alteratives, such as mercury and potassium iodide, were perfectly useless and the only drug which gave any considerable relief was opium in the form of liquor morphinæ or chlorodyne. Spinal puncture in the lumbar region and the removal of as much spinal fluid as would flow away of itself without aspiration probably relieved cerebral pressure and certainly relieved symptoms for a time in some cases. The steps of this small operation need not be described, he thought, but the needle used should be about 3½ inches long for comfortable use on an adult and about 2½ inches for a small child, and they should be of good calibre. He had usually found that the needle penetrated the spinal canal at a depth of about 2½ inches in the adult and about 1–1½ inches in the infant, but that naturally depended on the muscular development; fluid generally flowed freely as soon as the needle entered the canal but should it not do so a stylet might be passed down the needle to clear it of any possible clot; it was frequently clear and limpid in severe cases of the disease. Anti-meningitis serums had not been tried on any cases in West Africa; their preparation and use required the utmost care and skill and conditions of surgical cleanliness which were at present unattainable so far from the coast as the infected districts of the Northern Territories. In Europe at least three separate kinds of such serum had been tried and discarded as of no avail, but recently a serum had been prepared by Flexner and Jobling of the Rockefeller Institute for Medical Research, New York, which had been tried in the Belfast epidemic apparently with good results, the mortality being reduced from 72 per cent. to about 25 per cent. Judgment as to its proper value must be withheld until further results were known, but it was possible that a serum of this nature might be of considerable value in West Africa in any future epidemic if it could possibly withstand the journey and climate. The diagnosis was usually clear but might be doubtful in subacute or chronic forms and in atypical cases. Constant headache, usually occipital, some stiffness of the neck with possibly very slight retraction of the head and tendency to orthotonos, and pain or hyperæsthesia over the spine were usually found. Kernig's sign was of great importance and pathognomonic of meningitis, but he had seen undoubted cases in which it had been very slightly marked or absent. The knee-jerk was frequently difficult to obtain in natives, but if exaggerated in one or both legs was worthy of consideration in conjunction with other symptoms as confirmative evidence. Ocular symptoms, such as ptosis or momentary spasmodic squint, should be looked for. Spinal puncture and the recognition of the meningococcus would settle the diagnosis. The history of the case and the presence of others with more marked symptoms would probably help, especially in such cases as infantile pneumonias. The symptoms of the malignant form were very like those of siriasis or sunstroke, but apart from the fact that these cases occurred mostly before the hottest part of the year (March to April), the dry climate of the dry season, the comparatively open country about 500 miles from the coast line, and the altitude (about 1000 feet above sea level) rendered it unlikely that sunstroke was the cause, while the presence of cerebro-spinal meningitis in other forms left little doubt that the symptoms were due to the latter. The steps taken to limit so far as possible the spread of the epidemic were:—1. Notification by the chiefs of the villages to the nearest medical officer of all cases of sudden death and of increase in the rate of mortality among their people. 2. Isolation hospitals, temporary or permanent, were erected in stations in suitable places, roughly in the infected districts, because it is contrary to theory and because we know of no mechanism whereby the body cells could communicate their modifications to the germ plasm. But ought the door to be slammed in the face of further inquiry? Is there not still here a legitimate field for observation?

At first sight there appears to be a glaring instance of such transmission—that is, syphilis—but this is dealt with as follows. Either the child imbibes the virus in utero by the placenta from an infected mother—this is evidently an antenatal infection rather than inheritance—or else the virus is introduced by the sperm cells of the father at the very moment of conception; this, again, whatever it may appear to us, is to the biologist not inheritance but an infection of still earlier date than the last. Similarly, it is denied that there can be a true inheritance of any microbic disease whatever. Suppose we assent to that, yet susceptibility to such diseases, in either a plus or minus direction—that is, proclivity to them, or power of resistance to them—may be inherited. And may not such susceptibility be first acquired and then transmitted? When measles appeared in Fiji for the first time its ravages were far more severe there than among ourselves with whom it has long been endemic. The simplest explanation of this (I know there are others) seems to me to be that we have acquired and then perpetuated some degree of resistance to the disease. Suppose that a man of healthy stock acquires phthisis, will his children be more prone to phthisis or no? Our treasurer in his "Treatise on Gout" says "the fact of acquired gout must be accepted." Suppose, then, a man of healthy stock acquires gout, are his children likely to be gouty? Suppose, again, that a man in consequence of a blow on the head becomes, like Brown-Séquard's guinea-pigs, epileptic, is there any risk that his children will be epileptic? Suppose that a man has syphilis in early life and later becomes a general paralytic, ought we to feel more anxious about the mental future of children begotten during his last illness than about that of his earlier ones?

I confess for myself that I do not know the answer to these questions, but I think that there are those among my audience whose experience could supply it and who are well qualified to "search and study out this secret of nature," whether acquired diseases are in any degree transmissible to our children or no?

I must now refer, though in the briefest possible way, to the work of Mr. Francis Galton, Professor Karl Pearson, and those others who have enriched the study of heredity by the method of statistics, if only to express my admiration for their arduous labours. It may be that statistics do not appeal so forcibly as they ought to do to the medical man, because he has principally to deal with individuals. Neither have statistical methods, so far as I know, been largely applied as yet to the subject of heredity in disease. But nevertheless the general principles evolved from them must have their application for us. Thus the "law of ancestral inheritance" reminds us that we are hybrids—mongrels in an extreme degree—or to put it more pleasantly, that our inheritance is very composite, a patchwork or mosaic pieced together from the characters first of our two parents, next of our four grandparents, and then in a diminishing ratio from an almost infinite number of ancestors, who probably included all sorts and conditions of men. Secondly, the "law of filial regression or correlation" declares that although children resemble their parents in the main, nevertheless unless constant attention be given to breeding, there is a tendency among the descendants of any individual parent to smooth out any striking peculiarities he may have possessed, and to bring them, whether it be upwards or downwards, to the average level of his multitudinous ancestry. So that the average man cannot hope to escape mediocrity, unless, as the saying goes, he has been very careful in the choice of his ancestors.

But the mention of the word hybrid naturally leads our thoughts to the discoveries of Mendel. Now were romance permissible in a Harveian oration it might well be evoked by the story of Gregor Johann Mendel, peasant-born, priest by vocation, yet a student of science, and a man of rare scientific insight, whose life was spent as priest and as abbot at the monastery of Brünn, and whose leisure was spent in the study of hybridisation of plants. He died in 1884, unknown to scientific fame, and his work, buried in the proceedings of a local scientific society, was like to have died with him; but it has been disinterred in this century by those who recognise in it the hand of genius and compare it in importance to the work of a Newton or a Dalton.

It is to Professor Bateson that we in this country are chiefly indebted for the exposition and elaboration of Mendel's work. The principles of Mendelism, as it is now called, are admirably summarised in a little book by Mr. R. C. Punnett; I shall borrow from him and not tax your patience long.

Mendel showed that in the study of inheritance it was possible to select certain simple characters whose nature was more or less opposed, such as tallness and dwarfism, roughness and smoothness, colour differences and the like. These could be studied apart from other characters, and were found by him to behave in a definite way, as follows. Suppose a plant which is of a pure tall breed is fertilised from a similar breed, the resultant offspring is of course the same—viz., pure tall; and from a pure dwarf breed treated in the same way the results are pure dwarfs. If a pure tall, however, be fertilised from a pure dwarf, the result must be a generation of hybrids; and one might expect them to be of medium height. But this is not the case, they are all tall. It looks as if the tallness had swamped the dwarfism, so that we may call the tallness a dominant character and the dwarfism a recessive character. But though these hybrids are tall in appearance, the dwarf element has not wholly disappeared, it remains in respect of their powers of propagation. For if these tall hybrids be interbred together the dwarfism comes out again in their progeny, so that in the third generation there are some tall, some dwarf. Moreover, there is in this third generation a definite proportion between the two varieties—namely, three tall to one dwarf; or, to speak more accurately (as can be proved by further interbreeding), one pure tall, two hybrids which appear tall, and one pure dwarf. The theoretical interpretation of these facts is that the pairs of characters which behave in this way (allelo-morphic pairs as they are termed) do not blend in the germ cells or gametes, but that each gamete carries either one of the characters or the other; and further, that the difference between a pure breed and a half-breed is this, that in a pure breed all the gametes carry one of the characters to the complete exclusion of the other, while in a half-breed half the gametes carry one character and half carry the other.

Mendel made his classical experiments on plants; they have been repeated by other observers not only with plants but with many forms of animals—e.g., insects, snails, poultry, pigeons, rats, mice, and rabbits; and many characters have been studied from this point of view. One result may be quoted as specially interesting to physicians. It is that when a certain species of wheat which is very susceptible to the ravages of a fungus which causes "rust" is crossed with another species which is not susceptible, the immunity to rust which reappears in the resulting strains of wheat distributes itself in the Mendelian proportion. This suggests the possibility that something of the same sort may hold with respect to our own susceptibilities to disease, and raises the very questions which interest us most. For we want to know whether Mendelian laws are applicable to man, to his normal characteristics, and to conditions of disease, and how far they are applicable.

This question cannot be answered completely. Observations have been made (many of them I imagine under the inspiration of Professor Bateson) on various points, such as the colour of the iris by Mr. Hurst; hereditary diseases of the eye, such as congenital cataract, night blindness, and colour blindness by Mr. Nettleship; hæmophilia; albinism; alkaptonuria by Dr. Garrod; hereditary deformities of the limbs by Farabee and Drinkwater. Dr. Gossage has rightly drawn attention to the importance of hereditary diseases of the skin, which are easily observed, and has himself investigated the condition known as tylosis of the hands and feet. It would appear that in some cases the Mendelian proportion works out; in enough, perhaps, to encourage further research, but I do not know whether more can be definitely said. The difficulties are sufficiently obvious. The only method of inquiry at present open seems to be the patient collection of pedigrees; experiment is possible with plants and animals but not with mankind. We cannot pick parents to breed from. The pedigrees, too, must be complete, not only as to the number of diseased people but also as to the number of the normals, since the proportion between the two is a vital point. A pedigree should embrace at before it began to be ill adapted for its purpose. It became law in 1876, and it was in 1878 that Pasteur took part in that memorable discussion in the French Academy of Medicine on puerperal fever. Henceforward, of course, began the rapid increase of the number of experiments on animals which has risen continually ever since. In 1875 the evidence before the Royal Commission had mostly been technical, abstruse, occupied mainly with physiology, and hardly intelligible to the general reader. In 1906 the whole world was interested in bacteriology; public imagination had been caught and fired by the work of Pasteur and of Lister and of Koch. The discovery of diphtheria antitoxin and of thyroid extract, the mapping out of the motor areas of the brain, the protection of sheep and cattle against epidemic diseases, appealed to everybody. Then, above all, came the news of what was being done in tropical medicine. Men were taking their lives in their hands, and some of them had lost their lives, in India, on the Gold Coast, or in the Uganda Protectorate. Expedition after expedition was going out from Liverpool, more romantic than any adventurer in the days of Elizabeth, and infinitely more beneficent. How they fought the plague in India, how they stamped out the yellow fever in Havana, the malaria wherever the malaria was, and what they did for Texas cattle fever and for the tsetse fly disease—all these mighty works were read and believed. In brief, the works of science had come down at last, out of the laboratories, into the national life and the national conscience; and every man of science who had watched these wonders in the making, or had something to do with the making of them said, "Now, at last, this country is beginning to understand what it owes to experiments on animals. And we will use this Royal Commission for the education of the public; they shall have chapter and verse for everything; they shall have, for the first time in their lives, a careful and complete history of the Thirty Years War against disease." In brief, the men of science welcomed the present Commission with gladness because it was so exactly the very thing that they wanted. They had so much to tell the Commission, so many things that they wished to get into the public mind, that they had to be very careful to avoid the overlapping of evidence and all waste of precious time; so, on the appointment of a Commission a meeting was held of representatives of some 60 or 70 scientific or medical societies, and from these representatives a small executive committee was formed, with Professor Starling as chairman. It was the business of this committee to divide the whole history of modern experiments on animals, giving each witness a part of it; to be in recognised correspondence with the Royal Commission; and to watch and record the whole course of the inquiry. We owe it to Professor Starling's committee that the public possesses, in five large Blue-books, a most admirable history of all experimental medicine in this country back to the days of the 1875 Commission. Then when the present Commission, having sat from October, 1906, to March, 1908, and heard no less than 21,761 questions and answers, decided that they did not desire any further evidence, it seemed a pity that Professor Starling's committee should come to an end. There was need, so it seemed, for some association or society which should permanently remind the public of these facts about experiments on animals and should steadily oppose the antivivisection societies. Such a society might, it seemed, do good work without interfering in any way with the work of the Association for the Advancement of Medicine by Research. That association is privileged to advise the Home Office, and by virtue of that privilege is not a public or militant body. Therefore, at a meeting of Professor Starling's committee in January of the present year the Research Defence Society was founded. It began with seven members, which was a lucky number. It has now, October 8th, 1472 members, of whom 158 are ladies.

[Mr. Paget continued by describing the aims of the Research Defence Society which he said was first and foremost a society for telling the truth about a very important set of facts which have been saturated with falsehood. It existed to disseminate practical advice amongst the people in the interests of the national health, but especially to combat the mis-statements and slanders of the many antivivisection societies which had now for 30 years been fighting so hard not only against science but among themselves, and had received not much less than £80,000 and had accomplished next to nothing. He continued:] Against these societies, we now have a society which may truly be called representative of the collective good feeling, philanthropy, scientific mind, and passionate respect for plain facts which are no less admirable than our care for animals, and are even more necessary for the health and the strength of the national conscience. Thus, at last, we come to the work of the Research Defence Society. Its work is not only to defend the practice of research but to defend the honour of research. Our men of science have been grossly and most impudently insulted, and we are not going to stand that any longer. The British public is sick to death of hearing Pasteur called a torturer and Lister called a fool: sick to death of the platform facts, the placards, the public meetings, and quarrelling, and the incessant begging of these antivivisection societies. They have gone too far, they have talked too much, and at last they have defeated their own ends and everybody has got tired of them. The work of the Research Defence Society, therefore, is mostly, if I may dare to use the word, apostolic. It is willing always to send a representative to any straightforward debate, and even to meet at such a debate the representative of an antivivisection society. Only it draws the line, very properly, at accepting challenges from antivivisection societies or at arranging debates with them. It is also willing to arrange with any literary society or institute for the giving of a lecture or address which would be open to fair discussion. But its more immediate daily business is the sending to all applicants of the pamphlets and the leaflets already issued. Bound copies of these pamphlets have lately been sent to all the chief public or educational libraries in London and in our great provincial towns. But, of course, it is nothing to send a book to a public library in a place like Manchester or Bournemouth. What is everything is a branch society in every great town in England, spreading in that town a more general knowledge of the facts about experiments on animals. Finally, as it is the privilege of a new society to be ambitious and to look far afield for the extension of its work, so the Research Defence Society has been in communication with some of the most eminent American physicians and surgeons; and steps have now been taken in regard to the formation of a Research Defence Society in the United States.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Oct. 15th, Mr. D'Arcy Power, the President, being in the chair.—The proceedings commenced with a discussion on two proposed alterations in the rules of the society: 1. It was proposed "that smoking be allowed at ordinary meetings." This motion on being put to the vote was not carried, a majority of members voting against the suggested change. 2. It was proposed "that gentlemen who possess a dental diploma of the United Kingdom and who are on the Dental Register shall be eligible for membership of the society." This motion was carried and the rules of the society will be amended accordingly.—The President then showed a case in which he had Removed the Spleen by Operation, the spleen having been ruptured by an abdominal injury. The patient had made a complete recovery.—Dr. Sidney P. Phillips showed a case of Left Hemiplegia in a boy. There were complete optic atrophy and choroiditis with blindness. There was marked athetosis on the left side and defective articulation was present. The condition was the result of cerebral thrombosis associated with congenital syphilis.—Dr. Phillips also showed a case of Transverse Myelitis in a boy. The lesion was in the lower dorsal region. The patient had much improved under treatment and was now able to walk. Spastic paraplegia and incontinence were still present.—Dr. W. H. Willcox showed a case of Hæmophilia in a man, aged 26 years. The patient had been under treatment for five years. Unless calcium and magnesium salts were given from time to time the coagulability of the blood fell to below the normal and bleeding occurred. The attacks of bleeding were now less frequent and much less severe.—Dr. Willcox also showed a case of Hæmoptysis in a boy whose brother suffered from hæmophilia. The patient had apical pleurisy and also some slight pleurisy in the left axilla. It was thought that the hæmoptysis was due to pulmonary tuberculosis and not to hæmophilia.—Cases were also shown by Sir John Broadbent, disease which must have existed potentially all his life. The date of onset may be influenced, too, within limits, by family proclivity or circumstances; in a series of brothers and sisters it often repeats itself.

Now, though the presence of a definite organic lesion and a progressive downward course are the rule for these complaints, this is not so for all of them. Contrast the hereditary chorea of Huntington, which is fatal and in which lesions of the cortex have been found by Michell Clarke and others, with family tremor, which is not necessarily progressive and for which we know no anatomical basis. Contrast, too, in this respect, muscular dystrophy which may slowly reduce a patient to the condition of a living skeleton with the perverted condition of muscular contraction known as myotonia congenita or Thomsen's disease.

Notice, too, that most remarkable family disease called "periodic paralysis," in which the patient experiences recurrent attacks of paralysis, so complete that even the electrical reactions of the muscles disappear; yet the attack passes off and he is well in the intervals. This affection has been traced back through as many as five generations. There can hardly be a gross lesion; and the suggestion has been made that some poison is at work, perhaps produced by the patient's own faulty metabolism; an "inborn error of metabolism," like those with which our Croonian lecturer, Dr. A. E. Garrod, has made us acquainted.

In these family nervous diseases the curious phenomenon of sex limitation is sometimes seen, and generally in this sort, that females are themselves not affected, yet they transmit the disease. This was pointed out, I think, by Sir William Gowers, in pseudo-hypertrophic paralysis, and in the remarkable pedigree of peroneal atrophy published by Dr. W. P. Herringham in 1889 it is a striking fact. Yet in peroneal atrophy it is certainly not the rule; and in sundry other family diseases I do not think it occurs at all.

Lastly, as to the essential nature of these diseases. They have been called family diseases, if I mistake not, in order to avoid the distinct assertion that they are hereditary—i.e., *transmitted from ancestors*. But why should we not assert this? It is true that such disease may break out in a family of brothers and sisters without obvious ancestral taint; but in all these instances there is an absence of other sufficient cause, and they can be supplemented by quoting other families in which we know the disease to have been handed down. How, too, when *cousins* are affected? The common cause must then lie further back than the parents or the upbringing of one particular family. Indeed, if we refuse to call these complaints hereditary because we cannot always trace the heredity we should on the same ground refuse to call them family affections. For we often meet with isolated instances, sporadic cases where only one member of a family is affected. This is surprisingly frequent in Friedreich's disease. Still, it is a strange thing to witness, when a disease, hitherto unknown in a family, arises without apparent cause, and involves in a progressive paralysis one after another of the brothers and sisters. What shall we call it? is it a "mutation," a biological "sport"? Is the germ plasm just trying a change, stimulated, it may be, by some untoward circumstance, such (let us say) as alcoholism in the father? Or shall we suppose that the disease has been in the ancestry all along, but hidden away as a "recessive" character, so that if we could push our researches far enough back we might find it? Let us remember the remarkable account given by Rutimeyer where no less than *four families of cousins* (in various degrees) were affected by Friedreich's disease, a sure enough indication that there was some ancestral taint. Yet no case could be found among the ancestry till in the fifth generation a record was found of their common great-great-great-grandfather who, on account of his unsteady gait, had been nicknamed the "Stumbler."

As to the actual pedigrees of these family paralyses we are beginning now to acquire some tolerably complete ones, and it might be thought that this is just the class of disease which would lend itself to a Mendelian explanation. But I understand that there are considerable difficulties about this: so much, indeed, that it has been suggested that parental infection and not heredity is the real cause. But what infection could pass down for several generations, sometimes skipping a generation, sometimes limiting itself to the male sex? For myself I cannot imagine that, and I think that the key to this lock must be provided by the laws of heredity, whatever these laws may be.

But I fear, Sir, that in pursuing the subject of heredity I have already wandered too far. How shall I, in conclusion, come back to Harvey and to the College which he loved so well? Harvey himself in the presence of a great subject did not shrink from metaphor. He spoke of bodily conceptions and of conceptions of the mind almost as if they were one, and in speaking of the generation and inheritance of ideas he says Democritus and Eudoxus "impregnated" Epicurus and the four elements of Empedocles Aristotle. Is it, then, too fanciful to ask, How does this College reproduce itself and what laws of inheritance are at work within it from generation to generation? Now we are told that Nature has reserved the work of reproduction to herself and left parents little to do in determining the inborn characteristics of their offspring, but we in this College have the privilege of actually choosing our successors. This inestimable privilege we delegate to no one, not even to a body of examiners, and we choose our new Fellows by coöption, the best of methods when well exercised, the worst when exercised badly. Rightly, then, are we reminded each year of the responsibility which rests upon each of us in this respect, and rightly is that meeting of the Council in which recommendations for the Fellowship are winnowed out held to be of supreme importance. Is there then no continuity in the successive generations of the College? Does each depend on the mere caprice or individual likings of its predecessor? No; for we, too, have our "germinal plasm" which is continuous and everlasting; I mean *the noble principles upon which the College is founded* and by which it has ever been maintained—zeal for the pursuit of truth whether in medicine or in other science; the dedication of knowledge thus acquired to the relief of human sickness and pain; *self-effacement in the interests of* the profession and of the College to which we belong; and, above all, the spirit of unity and amity. For Harvey's last and best exhortation is "to continue in mutual love and affection among ourselves"; an exhortation which he enforces with the weighty words: "Concordiâ res parvæ crescunt, discordiâ magnæ dilabuntur."

An Inaugural Address

ON

THE LIMITS OF KNOWLEDGE.

Delivered before the Medical Faculty of the McGill University, Montreal, on Sept. 22nd, 1908.

BY G. A. GIBSON, M.D. EDIN., LL.D. ST. AND.
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

MR. VICE-CHANCELLOR, MR. DEAN, LADIES, AND GENTLEMEN,—Such an honour as that which the *faculty* vouchsafed to me in the request to address you to-day led, as you may readily believe, to much searching of heart. At the first blush the prospect seemed too alluring to be foregone; second thoughts followed, burdened with doubts whether it would be possible to rise equal to the demands of the occasion; these, however, in turn faded before the feeling that the only fitting acknowledgment of your kindness lay in yielding to your wish.

It is indeed a source of much pleasure to be again amidst the fair scenes of this great Dominion, and to dwell upon the manifold beauties showered upon her by the ungrudging hand of Nature. It is delightful to gaze once more upon the broad bosom of the silver river with its emerald jewels, reflecting the glowing tints of the woods in their winsome robes. It was amongst these lovely scenes that the thrilling pictures of Parkman first held me in thrall and led me to understand, as would in no other way have been possible, the lives and works of those who, during two centuries of conflict, strove for the mastery of the new world. Here also was borne in upon me the full meaning of the charming tales of Parker, and amidst their natural surroundings the characters whose loves and hates throb in his pages took an even more living form. Under the witching wand of *these* and many other wonder workers who have lived in your midst, the ground is hallowed by thoughts of the past. What a marvellous vista it is! The brave stealthily gliding through the primæval forest; the pioneer pushing farther into the Western fastnesses; the diagnosis of bone disease radiograms are useless unless this texture can be properly studied. Past books on the subject have usually erred in this respect and have therefore been of little use to the practitioner who is unable to study a series of radiograms first-hand. We can therefore confidently recommend this book to those who wish to study the subject of differential diagnosis of diseases of bone by means of the x rays, a subject which has so far been comparatively neglected. With a knowledge of the subject such as this book confers it is comparatively easy to say whether osteitis is tuberculous, syphilitic, or due to the other more virulent pyogenic organisms, and to differentiate inflammatory swellings from tumours of bone, a boon which no other method of examination confers with half the same certainty. We recommend it specially to those who have to deal with large numbers of obscure cases of diseases of bones and joints in the out-patient departments of the large hospitals.

The book is worth buying as the plates are accurate records of typical pathological conditions and can therefore not get out of date. Nor is modern printing likely to reproduce such plates any more accurately in the future. The plates could hardly be better done.

Essentials of Physiology for Veterinary Students. By D. NOËL PATON, M.D., B.Sc. Edin., F.R.C.P. Edin. Second edition. Profusely illustrated. London and Edinburgh: William Green and Sons. 1908. Pp. 464. Price 12*s.* net.

IN setting himself the task of writing a book on veterinary physiology Dr. Noël Paton has well earned the thanks of the veterinary community, both of students and practitioners. Realising the pressing need for a work of this nature he has brought to bear on the subject not only his knowledge as a professor of physiology but also the experience which he gained as examiner in the same subject appointed by the Royal College of Veterinary Surgeons. In this capacity he had from time to time before him the students for whose assistance he has now compiled the volume under review.

Careful reading of Dr. Paton's book conveys the impression that the author writes from the point of view of the scientific theorist. The trained veterinary practitioner whose life's work lies amongst the animals of the farm will disagree with some of the statements made. Thus we can find no mention of the fact that the horse possesses no gall-bladder. In speaking of this organ Dr. Paton would seem to give the impression that it is possessed by all animals, yet it is a fact which is of great clinical importance that the equine bile-duct has no diverticulum and consequently the bile dribbles continuously in small quantities into the bowel. We have only to consider this fact, associated as it is with small capacity of the stomach in this animal, to appreciate the necessity for feeding the horse frequently, and with small quantities each time, if we would keep it in health; recollecting, too, that it adapts itself to these inconveniences in the natural state by being a continuous feeder.

General physiology is fundamentally the same in both man and animals, and animal protoplasm is exactly the same as human. The circulatory system is the same in both, and the human nervous system only differs from the animal in being more highly developed. But in the alimentary tract we find great differences of structure and variations in the composition of the digestive juices. For the most part the author deals with this complex subject in a manner which leaves little to be desired. He states briefly the nature and comparative value of the various food-stuffs; he points out clearly the differences in value between the foods of the carnivora and the herbivora; and he describes the relation between the foods and the nature of the tract through which they pass. He demonstrates clearly in the text and by means of some excellent diagrams the anatomical peculiarities to be found in each animal. He describes the different processes through which the foods pass after being eaten, discussing their digestibility and energy value, the part which they play in the metabolic processes, and their ultimate fate in the tissues. All these matters are dealt with exhaustively yet without superfluity. Reproduction, the bugbear of the student, is rendered admirably clear and simple in the concluding pages of the work, the value of which would have been enhanced, however, if greater emphasis had been laid on the differences to be found in the placentation in the different animals.

Taking the book as a whole we feel sure that the information contained in it will be welcomed by the present-day veterinary student, and we venture to express a hope that when it comes to a third edition the wants in this direction of the veterinary practitioner may also be more fully dealt with especially in reference to the everyday occurrences which are met with in daily practice; in fact, if we may so use the term, we should like to see the book named a "clinical" veterinary physiology.

LIBRARY TABLE.

Diseases of the Genito-Urinary Organs and the Kidney. By ROBERT HOLMES GREENE, A.M., M.D., Professor of Genito-urinary Surgery, Medical Department of Fordham University; Genito-urinary Surgeon to the City and to the French Hospitals, New York City; and HARLOW BROOKS, M.D., Assistant Professor of Pathologic Anatomy, University and Bellevue Hospital Medical School; Visiting Physician to the City Hospital, New York City. With 292 illustrations. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 536. Price 21*s.* net.—In this work we have for the first time, so far as we are aware, a treatise on the genito-urinary system which has been written jointly by a surgeon and by a physician. Nearly the whole of the literature of this important department of therapeutics has been written from a surgical point of view, therefore it is well sometimes to have combined with this the medical aspect of the subject. We are also pleased to see that the urinary part of the genito-urinary system has received its due share of notice, for in many works on the subject sexual disorders have usurped more attention than they deserve. A good account is given of the instruments employed in the examination of the urinary organs, and we are inclined to agree with the authors that urinary segregators will give way to ureteral catheterisation. With the latter method the results are much more certain, though it is probable that less skill and experience are required in the employment of a urinary segregator. The authors speak favourably of massage of the kidney and ureter as an aid in diagnosis of suppurative nephritis. The method was introduced by Giordano of Venice and it deserves attention, but the cases in which it is likely to be useful are probably few in number. A very brief account is given of litholapaxy and the authors are mistaken in saying that Bigelow was the inventor of the evacuator, though he should certainly have the credit of extending its use greatly. The histology of hypertrophy of the prostate has been fully investigated by the authors and their conclusions are that the condition is certainly inflammatory, and they are inclined to attribute it in most cases to a posterior urethritis, usually of gonorrhœal origin. A good description is given of the perineal operation for enlarged prostate, but the account of the suprapubic operation is inadequate. We should like to know the evidence that the authors have for saying that the ordinary radical operation for hydrocele affects the function of the testis. They say: "By removing the tunica the natural covering of the testicle is destroyed, and it would seem to follow, as a matter of course, that the adhesion with subject pregnant with interest, showing how the grey dawn which we owe to the keen insight of the fathers of modern medicine has brightened into the morning light, how both sides of the world have been engaged upon it, every civilised country in a spirit of generous rivalry doing something to aid the efforts to reach the noontide of knowledge. It is a matter also full of encouragement, for it shows how much may be done by earnest men possessing apparently but small opportunities for original research. To some of us it is only vouchsafed to spin the thread and we have to learn to rejoice in cheerful vein when another weaves the web.

To the loyal worker in scientific fields it is enough if he feels that he is adding something to the general fund of knowledge. He may not be able to see at the time whither his observations lead, but he knows that, when joined to the results of other investigations, they will be useful. They may not be fitted to enter into the warp and the woof; the work of others may be of stronger stuff, for "the web of our life is of a mingled yarn, good and ill together." But even if they do not become woven into the finished fabric they have at least helped other labourers by the example they have shown.

Two of the great men who adorned Dublin during the first half of last century observed a group of symptoms which have in recent times been the object of close scrutiny. Adams, in one of the most remarkable of single contributions ever made to medicine, described infrequency of the pulse attended by apoplectic attacks in cases which presented the pathological appearances of fatty heart. He was followed by Stokes who, in adding further observations, noticed a want of harmony between the movements of the veins in the neck and of the arteries at the wrist; he stated, indeed, that the number of the venous pulsations was more than double that of the ventricular contractions. Stokes further described feeble sounds heard between the cardiac impulses. The meaning of these observations will be clear to us in the sequel. Many years passed before the observations of Adams and Stokes received any additions. It is true that a brief mention is made by Skoda of the subject, but new interest was not aroused until the appearance of some investigations by Leyden. The subject was afterwards discussed by Roy who ranged himself alongside of Leyden in favour of hemisystole as the cause of the want of harmony in the action of the veins and arteries.

To show how our various additions to knowledge are knit together it may be mentioned that almost immediately after the appearance of Roy's contribution a paper was published by Malet and myself in which we described the sound of the auricles in a healthy heart. The case was one of sternal fissure. Little did we think when placing this observation on record how it might afterwards prove fruitful. Linking it with the observations of Stokes, these isolated facts, apparently of no great value at the time, were afterwards found to be of real importance.

Some five years after our observation was placed on record Chauveau described a case of heart disease in which for the first time a dissociation of auricular and ventricular rhythm was carefully analysed by modern methods. This was followed by an excellent study in which Vaquez and Bureau still more clearly emphasised the lack of harmony between the movements of the auricles and ventricles. These investigations have been followed by the results obtained by a large number of observers, who, by means of clinical methods, have been able to demonstrate in the most complete manner that a partial or total dissociation may take place. It may seem almost invidious to single out any names in this connexion, but it is only right that we should honour those who have been pioneers in this field, and it is accordingly a pleasure to refer to the work of Moritz, His, Lichtheim, Mackenzie, Wenckebach, and Osler.

Besides obtaining such results in the investigation of the cardiac, arterial, and venous movements by the graphic method, it is full of interest to be able now to add that the sounds of auricular contraction have been over and over again heard by many observers in the intervals between the complete systole of the heart. These facts absolutely prove the correctness of Stokes's observations, and bring them into harmony with the physiological sounds described by Malet and myself.

Another addition to our knowledge of this interesting condition is due to Ritchie, Magee Finny, and Brouardel and Villaret, who, independently of each other, took advantage of the fluorescent screen in order to watch the movements of the heart. They published the interesting fact that the auricles can be seen beating in the intervals between ventricular systole. During the last three years this observation has been frequently repeated by other observers and is now well known.

Einthoven has taken advantage of the electromotive changes produced by the action of the heart, and by means of the string galvanometer has obtained beautiful tracings from cases of heart block which demonstrate beyond the possibility of doubt that the electromotive changes caused by the action of the auricles may be seen entirely dissociated from those caused by ventricular action. In ignorance of the important observations being made by Einthoven the electromotive changes in heart block simultaneously engaged my attention. My investigations were carried out with Lippmann's capillary electrometer. The movements of the column of mercury, thrown upon the screen by means of a projection microscope, showed the ordinary oscillations caused by the electric changes attending the apex beat, but, between these, smaller waves were distinctly visible and were undoubtedly produced by the contraction of the auricles.

One more clinical result obtained in this disease may be referred to before we pass on to the explanation of the condition. The arterial pressure in such cases has attracted my close attention. Observation on a good many cases has now proved that the systolic pressure may reach a level of from 270 to 300, while the diastolic may at the same time and in the same individual be as low as from 70 to 80 millimetres of mercury. This must be regarded as a most interesting fact, showing that the long interval of time following each ventricular contraction allows the high arterial pressure to fall to a low ebb before the succeeding systole occurs. It need scarcely be added that in such cases there is no aortic incompetence; nevertheless, clinical investigation of the arterial pressure yields results singularly like what we are accustomed to observe in that condition.

We have in this chain of investigations a really interesting illustration of the gradual evolution of clinical knowledge, and we must now enter upon the successive steps by means of which the different facts have been subjected to analysis and synthesis.

All of us who have sat on the upper forms at school must remember that the great epic poet of Rome tells of the happiness of him who is able to discern the causes of what he sees. The investigation of a series of appearances such as those that have now received our attention has furnished abundant interest, and therefore happiness, for all of us who have worked at the subject. Some points were found to be easy of explanation; others much more difficult. We have not merely to exercise the imagination in the search for these causes, but we may even invade the realm of speculation. It is a subject which allows opportunities to "spin the gossamer as well as forge the anchors of the mind." Our thoughts are not all endowed with the possibility of soaring to the very roof of heaven, but it is within the reach of us all to contribute what we can to the general advance and some of the suggestions, as well as many of the observations, are due to men deeply engaged in the hard work of general practice.

Until the last quarter of the previous century the heart was considered to consist of what might be termed distinct compartments, absolutely separated from each other and not united by any continuity of muscle fibres. The first light borne in on the subject came from the investigations of Gaskell who showed that there was a direct and continuous connexion of the sinus, the auricle, and the ventricle. It is exactly a quarter of a century since this great work made its appearance. Every succeeding observation has only served to prove more thoroughly the accuracy of the views which he then expressed, and to show the remarkable foresight which he manifested in his analysis of the various functions which he described. His investigations, in truth, have permitted the esoteric explanation of the condition at present under consideration. The facts unfolded by him formed, ten years afterwards, the subject of an interesting study by Stanley Kent, who, devoting attention more exclusively to the connecting link between the auricle and ventricle, showed the path by which impulses pass from the one to the other. His, in the same year, published his anatomical researches by which he

Poor-law Medical Officers.

THE terms and conditions of tenure of the members of the Poor-law medical service in England and Wales have lately been made the subjects of a carefully considered paper, read before the annual meeting of the Poor-law Medical Officers' Association of England and Wales by Dr. MAJOR GREENWOOD, its honorary secretary. The main object of the paper was avowedly to direct public attention to grievances affecting the personal interests of the officers concerned; but the author properly contends that these grievances are of such a nature as to place difficulties in the way of the complete discharge of duty by those whom they affect, and that they are therefore matters of public as well as of merely professional concern. They depend, for the most part, as we have on many occasions endeavoured to show, upon the fact that the conditions of the service have not been authoritatively reconsidered since 1847, although the intervening 60 years have been productive of many changes both in the duties to be performed and in the labour and expense incidental to performing them. It seems to have been the expectation of those who framed the regulations of 1847 that the stipends of the officers would be materially increased by fees for the surgical operations which from time to time they would be called upon to perform, and of which an official list was framed with a regulation fee attached to each operation. A few months only had then elapsed since the first operation under ether had been performed in London by Mr. LISTON, and neither the need for anæsthesia in surgery nor the enormous extension of operating which followed from it was in the least degree foreseen by anybody concerned. The operations chiefly required from parish medical officers were those for strangulated hernia and amputations; the equipment necessary for performing them was simple, and the prescribed fee might almost be regarded as remunerative when the conditions under which it became payable were considered. In the present day operations are constantly called for which have no place on the official list and for which no payment can be claimed as a matter of right, although the guardians may, if they see fit (which they seldom do), apply to the Local Government Board for permission to pay one. The operator is compelled to provide and to pay an anæsthetist at his own risk, and to provide also the costly equipment essential for the prevention of sepsis, with the ordinary result that the fee, even if any fee be paid, seldom covers more than the bare cost of the procedure, and certainly leaves no margin of profit capable of being regarded as a set-off against general insufficiency of stipend. The Local Government Board justly inclines to the opinion that it is better, as a rule, for pauper patients requiring serious operations to be removed to hospitals than to be treated in their own often miserable homes; but the justice of this view is largely dependent upon local conditions, roads, distances, facilities for conveyance, and the like, and can only be maintained by the admission of numerous exceptions to the rule. In certain cases of emergency the Poor-law medical officer must either operate or gravely imperil the life of his patient; and an operation, even when it is upon the official list, can no longer be regarded as a source of profit. In appendicitis, to take a single example from among many for which the list makes no provision, an operation may save a life which would have been lost by the intervention of a few hours and of a ten-mile journey, but the medical officer who performed it would have no legal claim for payment and could only receive a fee as a result of a special application made by the guardians to the Local Government Board.

Another grievance on Dr. GREENWOOD'S list is that of the remarkable inequalities which obtain between the rates of payment made to Poor-law medical officers in different localities. The extremes range, according to his figures, from 3*d.* a case to 20*s.*; and the most probable explanation of these discrepancies seems to be that great changes of population may have occurred in certain districts since the time when the amounts of the several stipends were fixed. Another and a more serious grievance arises from the necessity for the intervention of a relieving officer and the receipt from him of an "order" before the medical officer can claim payment from the guardians for his attendance upon a lying-in case, however urgent may have been the demand for his services. This question is already a pressing one under the operation of the Midwives Act, by which licensed women are required to send for medical assistance in certain conditions, and it will become still more pressing when that Act is completely enforced in 1910. Dr. GREENWOOD suggests, quite reasonably, that in all obstetric cases the Poor-law medical officer, and we would even add any medical man who attended in an emergency, should have a legal claim upon the guardians (or perhaps upon the local midwifery authority) for a specified fee, which the authority concerned should in proper cases be entitled to recover from the father of the child or other responsible person. But perhaps the greatest grievance of all, on which we have dwelt on former occasions and which has recently been brought into prominence by the action of the Driffield board of guardians in the case of Dr. A. T. BRAND, is that some boards regard the appointment of public vaccinator as one to be used as a counterpoise to the insufficient payment of the Poor-law medical officer, and so not only habitually confer both offices upon the same person, but, in the event of his resigning his Poor-law office, dismiss him from that of public vaccinator, in which his conduct may have been exemplary but of which he has no security of tenure. It is alleged that by means of this expedient Poor-law medical officers are induced to accept stipends which otherwise they would refuse, and there can be no doubt that this is the case in some instances. The use thus made by some guardians of the fact that the vaccination fees in their districts are considerable is obviously utterly immoral and tends to the total being independent of the wonderful and beautiful arrangement of nerve ganglia and nerve fibres, as also with their intimate connexions with the central nervous system. To suit these hypotheses the nervous system is allowed to interfere with, but has no part in, the production of cardiac action. Is this not a strange departure from the deep saying of Galen that "Nature does nothing imperfectly or vainly"? But this is a matter with which on the present occasion there is no time to deal. Suffice it to say that there is no proof of these assertions. Last year the subject occupied my attention in the oration of the Medical Society of London, and it was a sincere pleasure to be able to range myself beside your professor of physiology, who a few weeks before in an eloquent address gave a powerful indictment of the fallacies of the myogenesists It is unlikely that any man of science with balanced mind will commit himself to the tenets either of the myogenetic or of the neurogenetic school. We must wait for more light before we are in a position to dogmatise on this matter. "Far more of our mistakes," says Matthew Arnold, "come from want of fresh knowledge than from want of correct reasoning." The intolerance which has been shown by the protagonists on both sides as regards this question makes many of us doubt whether the "tart apostle of sweet reasonableness" was right in his remark. New facts will be gained which will help us to reach more definite conclusions as to the esoteric meaning of cardiac activity, and until we are in possession of such facts we must keep our judgment in reserve. Hence the title chosen for this address.

A few words, addressed more especially to the undergraduates of the University, may in the last place be allowed me. These must be taken as coming from an older to younger brothers. You will not expect me, in the terms of a certain school of theology, to "improve the occasion." If you do you will be disappointed. The purpose of the remarks which have been made is to bring some aspects of modern research before you, to hearten you in your studies, but at the same time to warn you of the dangers which may attend them. We have seen in one small field of the vast domain of medical study that many industrious labourers have been engaged upon the matter; that the gradual growth of knowledge has taken place by separate additions made by patient observers, and that it is within the power of each and all of us to contribute to the store of information. In all this you have great encouragement for your work to come. The illustration chosen is only a single example of what you will find in every branch of science. The first aim of every one of us must be to strive after fitness for the task which each will find. Again, one of the clearest duties lying to one's hand is to discover in which direction practical usefulness may most likely be found. In the present age omniscience cannot be our foible and a wise choice of study is an absolute necessity. To be able to grasp the real and eschew the unreal is the first requisite of him who is in quest of truth. You will be guided in your early footsteps by men of experience and distinction, who will help you to gain an insight into what is worth study. In this way you will escape the risk of resembling the dull pedant of whom the American humorist sings:—

> "A reading machine ever wound up and going,
> He mastered whatever was not worth the knowing."

In the search for truer interpretations of natural appearances we must train ourselves to build our foundations on the solid bed-rock of fact. Blowing hypothetical bubbles will not avail. It would be foreign to the genius of my race to contemn philosophical reasoning, but it is nevertheless a duty to condemn baseless speculation. Imagination rightly used is of the highest value in science,

> "But not for golden fancies iron truths make room."

The scientific method is, as Huxley has clearly stated, "Nothing but trained and organised common sense, differing from the latter only as a veteran may differ from a raw recruit." No one can successfully dispute this statement and probably few will make the attempt. There is no need for me to dwell on this theme, but it will not be out of place to add that this quality of common sense is not the possession of mankind in equal proportions. To some it has been granted in fuller measure than to others, but to most men a fair share has fallen. It is one of our first duties to listen for the whisper of this inborn wisdom or common sense which must be our final guide in all our work. May we not without any great strain apply to this gentle voice the words of an early English poet who died just 400 years ago?

> "The vertue of her goodly speche,
> Is verily myne hartes leche."

Goethe long ago frankly said that in his old age he had found it hard to be as wise as he had been in youth. This is a brilliant paradox the meaning of which is clear so that he who runs may read. But there is another side to the shield. It is within the reach of all of us to train this inherent quality by the discipline of experience. There is but one way in which this can be done: the way of hard work. In this age of strenuous endeavour it seems unnecessary to emphasise this gospel. It has been preached by many modern writers from Carlyle to Kipling, and the nobility of work in every field is now universally recognised. Upon us, most of whom are or will be concerned with the practical duties of serving our fellow men, it is incumbent to remember to what a high calling we are devoting ourselves. We have to enter into the lives of others in the fellowship of suffering as well as the brotherhood of happiness. "Man is the only book of life," says Pierre, and in this saying of Parker's interesting creation there is deep significance. It is our privilege, above all other men, to have the leaves of this book opened to us, and we must fit ourselves for its study.

In all our doings we must spend our lives in truth, faith, hope, love—clinging to that mood of mind, bent on winning to the very heart of everything; believing in real work as the means whereby in its own good time what is now hidden will be laid bare, trusting that the end of our quest will be the furtherance of knowledge and the good of mankind, and holding each of our fellow workers in such kindly thought as will lead us to be happy when any of them makes a forward step. May each of us be able to say in the words of a historic rascal, who yet had the elements of good in him, François Villon: "En ceste foy je veuil vivre et mourir."

An Address

ON

SANITATION IN INDIA.

Delivered before the Sanitary Conference of the United Provinces of Agra and Oudh at Naini Tal on Sept. 4th, 1908,

BY SIR J. PRESCOTT HEWETT, K.C.S.I.,

LIEUTENANT-GOVERNOR OF THE UNITED PROVINCES.

GENTLEMEN,—I am here to welcome you this morning on your assembling in reply to the invitation issued in this Government's resolution of the 6th ultimo with the object of undertaking a comprehensive discussion as to the manner in which sanitary reform should be prosecuted in the United Provinces. We aim at trying to devise some scheme by which, in course of time, the conditions of life may be made healthier for the residents both of towns and villages within the province; we seek some means of giving our men and women more strength and vigour with which to undertake their duties in life and to earn their daily bread, of making their days longer in the land, of endowing them with more stamina, and of insuring for them greater power of resisting disease so as to make them more fit for every form of employment, whether it calls into operation manual strength or the faculties of the mind.

The first thing that must strike every observer is that, cleanly as are the habits of a very large number of the people of India individually, they are very prone to ignore what has been well described as coöperative sanitation. Cleanliness of person and of the habitation constitutes only part of the precautions needful to insure protection against disease, and is wholly ineffective by itself if the house is inadequately provided with light and ventilation, and if the out-of-door surroundings and the air that is breathed outside it are contaminated and infective. You have to examine the whole question of how we can improve the sanitary conditions of life throughout our province, to try to determine whether what has been done in attempting this in the past (for a

Poor-law Medical Officers.

THE terms and conditions of tenure of the members of the Poor-law medical service in England and Wales have lately been made the subjects of a carefully considered paper, read before the annual meeting of the Poor-law Medical Officers' Association of England and Wales by Dr. MAJOR GREENWOOD, its honorary secretary. The main object of the paper was avowedly to direct public attention to grievances affecting the personal interests of the officers concerned; but the author properly contends that these grievances are of such a nature as to place difficulties in the way of the complete discharge of duty by those whom they affect, and that they are therefore matters of public as well as of merely professional concern. They depend, for the most part, as we have on many occasions endeavoured to show, upon the fact that the conditions of the service have not been authoritatively reconsidered since 1847, although the intervening 60 years have been productive of many changes both in the duties to be performed and in the labour and expense incidental to performing them. It seems to have been the expectation of those who framed the regulations of 1847 that the stipends of the officers would be materially increased by fees for the surgical operations which from time to time they would be called upon to perform, and of which an official list was framed with a regulation fee attached to each operation. A few months only had then elapsed since the first operation under ether had been performed in London by Mr. LISTON, and neither the need for anæsthesia in surgery nor the enormous extension of operating which followed from it was in the least degree foreseen by anybody concerned. The operations chiefly required from parish medical officers were those for strangulated hernia and amputations; the equipment necessary for performing them was simple, and the prescribed fee might almost be regarded as remunerative when the conditions under which it became payable were considered. In the present day operations are constantly called for which have no place on the official list and for which no payment can be claimed as a matter of right, although the guardians may, if they see fit (which they seldom do), apply to the Local Government Board for permission to pay one. The operator is compelled to provide and to pay an anæsthetist at his own risk, and to provide also the costly equipment essential for the prevention of sepsis, with the ordinary result that the fee, even if any fee be paid, seldom covers more than the bare cost of the procedure, and certainly leaves no margin of profit capable of being regarded as a set-off against general insufficiency of stipend. The Local Government Board justly inclines to the opinion that it is better, as a rule, for pauper patients requiring serious operations to be removed to hospitals than to be treated in their own often miserable homes; but the justice of this view is largely dependent upon local conditions, roads, distances, facilities for conveyance, and the like, and can only be maintained by the admission of numerous exceptions to the rule. In certain cases of emergency the Poor-law medical officer must either operate or gravely imperil the life of his patient; and an operation, even when it is upon the official list, can no longer be regarded as a source of profit. In appendicitis, to take a single example from among many for which the list makes no provision, an operation may save a life which would have been lost by the intervention of a few hours and of a ten-mile journey, but the medical officer who performed it would have no legal claim for payment and could only receive a fee as a result of a special application made by the guardians to the Local Government Board.

Another grievance on Dr. GREENWOOD'S list is that of the remarkable inequalities which obtain between the rates of payment made to Poor-law medical officers in different localities. The extremes range, according to his figures, from 3*d*. a case to 20*s*.; and the most probable explanation of these discrepancies seems to be that great changes of population may have occurred in certain districts since the time when the amounts of the several stipends were fixed. Another and a more serious grievance arises from the necessity for the intervention of a relieving officer and the receipt from him of an "order" before the medical officer can claim payment from the guardians for his attendance upon a lying-in case, however urgent may have been the demand for his services. This question is already a pressing one under the operation of the Midwives Act, by which licensed women are required to send for medical assistance in certain conditions, and it will become still more pressing when that Act is completely enforced in 1910. Dr. GREENWOOD suggests, quite reasonably, that in all obstetric cases the Poor-law medical officer, and we would even add any medical man who attended in an emergency, should have a legal claim upon the guardians (or perhaps upon the local midwifery authority) for a specified fee, which the authority concerned should in proper cases be entitled to recover from the father of the child or other responsible person. But perhaps the greatest grievance of all, on which we have dwelt on former occasions and which has recently been brought into prominence by the action of the Driffield board of guardians in the case of Dr. A. T. BRAND, is that some boards regard the appointment of public vaccinator as one to be used as a counterpoise to the insufficient payment of the Poor-law medical officer, and so not only habitually confer both offices upon the same person, but, in the event of his resigning his Poor-law office, dismiss him from that of public vaccinator, in which his conduct may have been exemplary but of which he has no security of tenure. It is alleged that by means of this expedient Poor-law medical officers are induced to accept stipends which otherwise they would refuse, and there can be no doubt that this is the case in some instances. The use thus made by some guardians of the fact that the vaccination fees in their districts are considerable is obviously utterly immoral and tends to the total

00 ; 52 per cent. live in villages of from 500 to 2000 ; 10 per ent. in villages of between 2000 and 5000 ; and 1 per ent. in villages of over 5000. There are 453 towns the opulation of which varies from 264,000 in Lucknow to a opulation of even less than 1000 and averages about 1,600. *These towns are differentiated according as they come* nder the Municipalities Act, the Act dealing with notified reas that were once but have ceased to be municipalities, nd Act XX. of 1856, an Act to regulate police and sanitaion in the smallest towns. The Village Sanitation Act pplies to certain rural areas ; at present it extends to some 00 villages with a population of 2000 or more. In areas ther than those under the Municipalities Act or notified reas there is no compulsory registration of vital statistics by private persons. In rural areas the village watchman reports births and deaths on his periodical visits (usually twice a week) to the police stations. In the towns under Act XX. of 1856 registration is effected by the chaukidars employed under the Act, and in municipalities and notified areas there is compulsory registration. Returns are obtained in some towns from non-official practitioners differentiating the cause of death, but an enormous majority of the reports of deaths are made by an illiterate agency utterly incapable of discriminating as to the cause of death.

In the past 25 years there has been large expenditure within municipalities on sanitary improvement: 113 lakhs of rupees (over £750,000) have been spent on capital outlay, and 57 lakhs (£380,000) on establishment and repairs in connexion with the water-supply; the capital outlay on drainage works has been 57 lakhs (£380,000) and that on establishment and repairs nearly 13 lakhs (£86,000). Expenditure on conservancy has been 215 lakhs (£1,430,000). In rural tracts and smaller towns expenditure has been on a very limited scale. In six of the seven cities with a population of over 100,000 as much as 292 lakhs (£1,950,000) have been expended on these objects, on vaccination, the improvement of markets, and protection against plague. In spite of all this expenditure the death-rates now reported in some of these cities are higher then they were before. Even if allowance be made for better reporting it is still impossible to gain consolation from the returns.

Still, in the matter of the restriction of diseases against which special measures have been taken both in towns and villages, such as cholera and small-pox, there is room for congratulation on the results achieved. The improvement in the water-supply in cities, the use of permanganate of potassium in wells and of Nesfield's powders have all contributed to reduce the mortality from cholera. This is a disease the deaths from which are returned with fair accuracy. It used to be very virulent among the troops 20 years ago, but a serious outbreak in a regiment is now of rare occurrence. The disease is now usually sporadic and is often due to food contamination by flies. The average death-rate from this cause between 1882–91 was 1·68 per 1000, between 1892–1901 1·49 per 1000, and between 1901–07 1·30 per 1000. In the famine year of 1896-97 the death-rate from this cause between September, 1896, and July, 1897, was 0·96; between November, 1907, and June, 1908, it was 0·72. There are only three districts in which famine camps have been seriously troubled with cholera this year. On the other hand, in some of the districts badly stricken with famine which have also suffered from epidemics of cholera it has been possible to protect the famine workers completely. Thus in the Bara Banki district over 3000 deaths were reported from cholera, but only two occurred on relief works; in the Gonda district there were 1900 deaths among the general population and only one on relief works. Here, at all events, there is direct evidence of the success of our sanitary department's work, and it is also to be found in the continued decline of deaths reported from dysentery and diarrhœa, a result which can fairly be attributed to the improvement of the water-supply. 50 years ago small-pox devastated the country and was specially prevalent in the hill tracts. So well protected are the latter now that the district of Garhwal has the highest vaccination rate and the lowest mortality from small-pox in the whole of British India. A great reform effected in recent years has been the substitution of glycerinated lymph for humanised lymph. The death-rate in the whole province from this disease was 1·26 between 1882–91, 0·33 between 1892–1901, and 0·25 between 1902–07. Here again there is indisputable proof of the good results achieved by the sanitary department in popularising vaccination.

The statistics under the head of fever are the reverse of encouraging. They do not indeed show how many people died from malaria, but they give an enhanced death-rate in each successive period of the past 25 years. Whatever the extent to which this may be due to better reporting it is *most discouraging that the death-rate* reported between 1882–91 (24·41) should have risen in the next decade to 25·21, and in the five years between 1902–07 to 26·49. The last figure is an appalling one. It is swelled by lung affections, tuberculosis of all kinds, and (during the past few years) by undiagnosed plague. But after making allowance for all these causes the number of deaths due to malaria is terribly high. Great strides have been made in the investigation of this disease in recent years. The only way known to science for the propagation of malaria is by infection through the bite of the anopheles mosquito. The *layman whatever he may think about the possibility of* malaria being contracted in other ways must accept the view of science that so far none other has been discovered. Such action as the executive government can take then must be based on the view that what we have to aim at is the restriction of the dissemination of malaria by the anopheles mosquito. I propose to place a medical officer on duty at once to investigate the liability of certain tracts in this province to malaria and to endeavour by special measures, such as the filling up of excavations and other irregularities in the soil, treating mosquito breeding grounds with kerosine oil, the free distribution of quinine, and inducing the better classes to protect themselves from mosquito bites by mechanical means to see whether we cannot effect a reduction in the incidence of the disease in these specially affected tracts. This is only one method of attacking the question of how to check malaria, and I hope you will give the problem of how to fight it your earnest attention. I do not propose on this occasion to say much about plague. Between its recognition in Bombay in 1896 and the first year of the present century only 363 deaths were reported in this province from this cause. From 1901 to the end of 1907 the number reported in the province was 1,095,000. The statistics of this disease have recently been dealt with in a published resolution. During practically every month of the past year its attack has been feebler than for six years, and there is certainly hope that we have seen the worst of it.

Of all the vital statistics the most distressing are those relating to infantile mortality. These figures are the index of the sanitary state of a community. The reported annual death-rate of children under one year of age was 229 per 1000 infants born between 1891 and 1900. The figures for the past three years have been 263, 251, and 253 respectively. To some extent the increase has been due to epidemics of measles which have become prevalent in recent years. In the last three years the number of deaths reported to be due to such epidemics has been 22,000, 44,000, and 80,000 respectively. But, whatever the cause, it is lamentable that one out of every four children born should die before he or she has completed a year of life. Infantile mortality is indeed enormous in every country. Even in England and Wales the annual death-rate was 153 per 1000 infants born between 1891 and 1900, and 132 in 1906. Here, as in England, the mortality among infants is higher in urban than in rural tracts, and specially high in industrial centres, where women work in factories and have to neglect the care of their young children. In Cawnpore the average death-rate during the past five years was 365 per 1000. In addition to the general difficulties in the matter of improving the sanitary surroundings of the people, we have here to contend with the immaturity and ignorance of the mothers, most of them being constantly employed on work both up to the child's birth and while they are suckling it, to the want of skilled midwives, to inadequate and dirty appliances used at the time of delivery with the result of inoculating the child with tetanus, to the prolonged period for which a child ordinarily remains at the breast, to the poor clothing of infants, to their exposure to various sources of infection, and to the neglect of the treatment of their diseases when they are attacked. This is truly a formidable list of obstacles to the growth of a child of the poorer classes to a healthy maturity; and many of them cannot be removed for a long time. But this should be no reason for our failure to look the problem in the face: to my mind it is the most important one to be attacked, if catholicity, subserved by the philosopher. No liberal calling, no career intellectual or moral, but has profited by his initiative and intervention. Apart from what he actually contributed to the common fund of ideas, the mere perusal of his writings is an exercise, a discipline, in what he himself finely calls "the Georgics of the Mind." Aye, and the lessons to be drawn from his own failings and positive misdeeds are fraught with admonition, as he would have been the first to own. Restricted in worldly means, while passionately devoted to the research for which such means were an indispensable pre-requisite, he did that which was unlawful, he even proved himself corrupt, he let himself lapse into evil "that good might come." Posterity, however, has been disposed to deal leniently with him—all the more that he practically says to it, "Reum habetis confitentem"; or, in his own pathetic words when commenting on his condemnation: "I was the justest judge that was in England these 50 years; but it was the justest censure in Parliament that was these 200 years." MACAULAY, interpreting the verdict of the nineteenth century, has given it noble expression: "Turn where we may, the trophies of that mighty intellect are full in view: we are judging MANLIUS in sight of the Capitol!"

BACON himself, as if to account for, not to justify, his own *peccata*, admonishes the reader that his "new instrument," while it will confer infinite and never-ending boons on mankind, will do this only in the material direction, leaving morality pretty much where it found it. Comfort, convenience, all that makes for the physical ease and well-being of humanity will go on increasing and multiplying, but on one side only of human development. "Let us not," said D'ISRAELI, "mistake Comfort for Civilisation," a witty and profound saying which RUSKIN was never tired of bringing home to a world exulting in its wealth and prone to the self-indulgence which wealth can favour. Take, he would say, the Platonic Trinity, the Beautiful, the True, the Good. In the first of these, are we superior, nay, are we equal, to the age that produced a PHIDIAS and PRAXITELES in sculpture, a ZEUXIS, a PARRHASIUS, and an APELLES in painting? In the second, are we one step nearer the solution of Knowing and Being than PLATO or ARISTOTLE, whose entrance into a modern metaphysical lecture-room would be more likely to embarrass the professor than to enlighten themselves? In the third, are not sin and crime a perennial quantity, more refined perhaps in their methods but not less real in their character than in ages when the steamship and the telegraph were unknown? Nay, are not these latter the instruments of despotism as much as of liberty, of the criminal as much as of the philanthropist? Questions these to be answered in the all-including Baconian sense, conveyed in the aphorism, "Man was made to mourn," which will be as true of him in the latter day as in the first! To the end of time humanity will have need of all its resources against the agencies of evil which have hitherto beset it; nor can an epoch yet be foreseen when the legal, the medical, and the ecclesiastical vocations will have died out for lack of employment. BACON, while enthusiastic in his estimate of the power of the "new instrument," did not omit to enter a caution as to its limitations—a caution not more needed in his own generation than in what a recent speaker, with unconscious humour, referred to as "this so-called twentieth century"!

The Pollution of Milk.

THE people of Chester are fortunate in the possession of a medical officer of health who is not only familiar with the dangers encountered by the community, by reason of the unsatisfactory methods of the production of milk in vogue amongst farmers generally, but who has the courage to speak plainly to his sanitary authority and to remind that body of its serious responsibility in connexion with this important subject. We have received from Dr. A. E. THOMAS, the health officer of Chester, an interesting pamphlet consisting of a reprint of a report submitted by him to his sanitary authority, in which he deals with the subject of the pollution of milk thoroughly and after a fashion which is in some respects original. The report has apparently been approved by the Chester city council, for it has ordered its publication for general distribution in the form now before us. The amount of money spent annually on the production of milk in the United Kingdom is enormous. "In round numbers" Dr. THOMAS computes it "at between 120 and 130 millions annually, or about two-thirds of the cost of the Boer War, about three-fourths of the national drink bill, and roughly about one-sixth of the National Debt." We proceed firstly to follow Dr. THOMAS, of necessity very briefly, in his description of the chief existing sources of the pollution of milk, based on his official experience in Chester and its neighbourhood, and then to notice his suggestions for the prevention of such pollution, for we believe that contamination of this commodity is by no means confined to the district referred to. Discussing the more common sources of the pollution of milk we are told that the problem of "clean milk" in all probability circles around the actual milker who is frequently the dirtiest individual in the cowshed; indeed, sometimes the cleanest is the cow itself. Among milkers he has observed general uncleanliness of the hands, finger-nails, face, and skin, filthy habits during milking, and the use of soiled clothes or fouled leather apron whilst milking, frequently a soiled equipment being reserved for this work alone. It is quite conceivable that the milker suffering from pulmonary tuberculosis may infect the milk or that patients who have been the subjects of enteric fever may some years later become sources of infection to others and may excrete daily countless numbers of specific germs. Obviously, therefore, it is desirable that persons in both the latter categories should be excluded from any department of the production of milk which exposes it to the risk of conveying infection. It is high time, says Dr. THOMAS, that the ignorant, dirty, careless milker was abolished and replaced by a clean and careful operator trained in one of the many dairy schools now established. It is not enough to provide washing basins, soap, towels, and nail brushes: it should be somebody's business to see that these are regularly used and that the milker does actually clean himself before milking. Very obvious is the influence of overcrowded, ill-ventilated, badly-road towards industrial progress throughout the land. The goal may appear to be far away, and indeed it is, but let us make a start on the road towards it; I feel sure that we could put no nobler aim before us.

NOTES OF A CASE IN WHICH NINE CONFINEMENTS WERE TERMINATED VARIOUSLY:—

(1) BY THE NATURAL POWERS; (2) BY SYMPHYSIOTOMY; (3) BY INDUCTION OF LABOUR AND FORCEPS; (4) BY FORCEPS ALONE; AND (5) BY CÆSAREAN SECTION.

BY ARTHUR H. N. LEWERS, M.D. LOND.,
F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

THE notes of the case are shortly as follows. The subject, now, in 1908, aged 34 years, has been married 16 years and has had nine children and one miscarriage.

First confinement.—This took place on March 2nd, 1892, at full term and the patient was delivered naturally. The child, a female, was said to have been small, and it died from wasting when four months old.

Second confinement.—This occurred on Feb. 12th, 1893. The patient was said to have been in labour for three days. The membranes ruptured at 2 A.M. on Feb. 12th. Attempts were made to deliver the child by the forceps at the patient's home but failed. She was admitted into the London Hospital under my care and I saw her at 9.30 A.M. The os was nearly, but not quite fully, dilated. The vertex was presenting in the fourth position and was definitely engaged. The fœtal heart was distinctly heard. The patient was having strong pains. Blood-stained urine was drawn off with the catheter. At 2 P.M. the os was fully dilated but there was no advance of the head. The caput succedaneum had increased in size and the fœtal heart was still audible. Chloroform was administered and a deliberate effort was made to effect delivery with the forceps, but it was found impossible to do so. Accordingly I performed symphysiotomy by the open method. Owing to an irregular projection in the line of the articulation the separation of the bones had to be completed with a saw. When the pubic bones were five centimetres apart the head was easily delivered with the forceps. The child, a male, was born alive and is at the present time (April, 1908) alive and well. Convalescence was long in being established, chiefly owing to incontinence of urine for some time after the operation and to the fact that the wound made by the symphysiotomy suppurated. A piece of dead bone was removed on March 25th. Ultimately the patient recovered complete control as regards the bladder and the operation wound healed soundly. The external measurements of the pelvis before the operation were as follows: between the anterior superior spines = 8¼ inches; maximum distance between the crests = 10⅜ inches; external conjugate = 6 to 6¼ inches. After the wound was soundly healed there was a vertical depressed cicatrix in the middle line in the region of the symphysis, and the external conjugate, when the anterior limb of the callipers was placed at the bottom of the cicatrix, was 5¾ inches. The other measurements were the same. So far as I can find, this symphysiotomy was the first to be performed in England since 1782, and the first successful one as regards its result. (See THE LANCET, August 5th, 1893, p. 300.)

The third confinement (January, 1895).—This took place in the London Hospital. Labour was induced at eight months and delivery was effected with the long forceps. The child was a female and is alive and well now (April, 1908).

The fourth confinement (Nov. 10th, 1896).—This also took place in the London Hospital. Labour started naturally at the eighth month. The presentation was the second vertex and delivery was effected with the forceps easily. The child, a male, is alive and well now (April, 1908).

The fifth confinement (Nov. 25th, 1898).—This also occurred in the London Hospital. Labour started naturally at eight and a half months. The presentation was the first vertex. Delivery was effected with much difficulty with the axis traction forceps and the child was stillborn.

The sixth confinement (Nov. 1st, 1899).—This also occurred in the London Hospital. Labour was induced at eight months. The presentation was the first vertex. Delivery was effected by the forceps with difficulty. The child, a female, weighed 6 pounds, and is alive and well now (April, 1908). The mother developed lobar pneumonia on the fourteenth day but ultimately did quite well.

The seventh confinement (Dec. 19th, 1901).—Labour began spontaneously at seven months. The patient was admitted into the London Hospital in labour; the breech and trunk were born in the receiving room and the arms in the corridor as she was being taken up to bed. The head was delivered with forceps as soon as she reached the ward. The child, a male, only lived 15 hours.

The next pregnancy terminated by a miscarriage at three and a half months. The patient did not come into the hospital but was treated at home and did quite well.

The eighth confinement (May 28th, 1903).—This occurred in the London Hospital. Labour was induced at eight months; the presentation was the third vertex. The child was stillborn.

The ninth confinement (Dec. 27th, 1904).—The patient was admitted into the hospital in labour. The vertex was presenting, the os was nearly fully dilated, and the membranes were unruptured. After rupturing the membranes the forceps was applied without success. Accordingly I performed Cæsarean section and delivered her of a male child which is alive and well now (April, 1908). With the view of rendering subsequent pregnancies unlikely I removed a portion of the Fallopian tube on each side. Up to the present there has been no other pregnancy, and as there has never been hitherto anything approaching such an interval as three and a half years between any of the pregnancies it seems as if what was done is proving effectual in this particular case.

The patient has now (April, 1908) five children living. Of these one was born by symphysiotomy, one by Cæsarean section, two by the induction of labour and forceps, and one by spontaneous premature labour and forceps.

As regards the four children she has lost, *one was born naturally*. This was the first. It is said to have been at full term, but the child was very small and died when four months old. Seeing how often labour began prematurely in her subsequent pregnancies, no less than three times, it seems not improbable that the first child was premature. *Two were born by spontaneous premature labour*, at eight and a half and seven months respectively, delivery being effected by forceps. The former was stillborn and the latter only

Table of the Nine Confinements.

Confinements.	Mode of delivery.	Sex of child.	Result as regards child.
First.	Natural labour at term. (March 2nd, 1892.)	Female.	Child died from wasting when 4 months old. Said to have been small and labour only lasted 6 hours.
Second.	Symphysiotomy at term. (Feb. 12th, 1893.)	Male.	Child alive and well, April, 1908.
Third.	Induction of labour at 8 months, forceps. (January, 1895.)	Female.	Child alive and well, April, 1908.
Fourth.	Spontaneous premature labour at 8 months. (Nov. 10th, 1896.) Forceps (easy).	Male.	Child alive and well, April, 1908.
Fifth.	Spontaneous premature labour at 8½ months. (Nov. 25th, 1898.) Axis traction forceps; very difficult.	No note.	Child stillborn.
Sixth.	Induction of labour at 8 months. (Nov. 1st, 1899.) Forceps (difficult).	Female.	Child alive and well now, April, 1908.
Seventh.	Spontaneous premature labour at 7 months. Breech. Forceps to head. (Dec. 19th, 1901.)	Male.	Child only lived 15 hours.
Eighth.	Induction of labour at 8 months; third vertex. (May 28th, 1903.)	No note.	Child stillborn.
Ninth.	Spontaneous labour at term. Forceps failed. Delivery by Cæsarean section. (Dec. 27th, 1904.)	Male.	Child alive and well, April, 1908.

Physicians was held in January of this year and a motion was carried that it was desirable that such alterations should be made in the by-laws as to allow the admission of women to the examinations of the College. This was carried by 74 votes to 33. When the Council of the Royal College of Surgeons was informed of this, it was decided to take a poll of the Fellows and Members of the College, and the result was that there was a majority of 415 against the proposal to admit women to the examination for the Membership and a majority of 1182 against admitting them to the Fellowship, 9451 Fellows and Members voting; when the votes of the Fellows were considered separately, it was found that the Fellows were in favour of the admission of women, though the majority in favour of admitting them to the Fellowship was only 34 out of 1034 who voted. It must be borne in mind that 13,812 circulars were sent out to the Fellows and Members and that more than 5000 were unanswered. On Thursday of last week the Council of the Royal College of Surgeons considered the matter finally and on the motion of Mr. Clinton T. Dent it was resolved to admit women candidates to all the examinations of the College. Two or three months will elapse before the necessary alterations can be made in the by-laws and the approval of the Home Secretary has to be obtained, but that will necessarily follow, so that women candidates will be admissible to all the examinations of both the Royal Colleges, including those of the Conjoint Examining Board for England. It was possible for the Royal College of Physicians to admit to the examination for the Membership, or for the Royal College of Surgeons to admit to the examinations for the Fellowship without the consent of the other College, but the consent of both was needed for the admission of women to the examinations of the Conjoint Board. It will be noticed that the Royal Colleges are admitting women under the Act of 1876 and the Royal College of Surgeons has taken counsel's opinion on the question of the voting powers of those women who obtain the Membership or the Fellowship of that College, and the opinion has been given that those women who obtain these diplomas will not possess any voting power. It was hoped by many Members of the College that the Council would apply for a new charter to enable it to admit women to the examination, and thus an opportunity would have been afforded for the Members of the College to obtain representation on the Council, but the action of the Council in utilising the Act of 1876 has frustrated this hope. It is of interest to consider the gradual change of opinion in this matter, and this is well shown by the voting at the meetings of the Royal College of Physicians. In 1877 the admission of women was negatived by 68 votes to 16; in 1895 the votes were 59 against and 50 in favour of the admission of women; and in 1908 the figures were 33 against the admission and 74 in favour. The only bodies possessing the power of granting qualifications to practise medicine and surgery which still decline to admit women to their examinations are the Universities of Oxford and Cambridge.

OLD AGE PENSIONS AND THE DESTITUTE.

AT the Hackney coroner's court on Oct. 17th Dr. W. Wynn Westcott held an inquest on the body of a crossing-sweeper, aged 77 years, who had been grossly neglected before he was admitted to the parochial infirmary suffering from a recent apoplexy. He was found in his single-room tenement in a very filthy state; indeed, maggots were seen crawling over his body. The coroner, having tried in vain to discover someone upon whom the responsibility for the care of the old man could be placed, instanced the case as an exemplification of his previously expressed opinion that the forthcoming old age pension would not be a certain benefit to those aged and feeble people who were without relatives who could, and would, help to look after them and keep them in a cleanly condition. With the proposed weekly grant of a pension of five shillings he was of opinion that, in London at any rate, the duties of the relieving officer and the work of the coroner would be greatly increased in so far as the aged poor were concerned. Five shillings were insufficient to pay for rent, fuel, food, and attention. Yet many old people would, while in receipt of this pension, absolutely decline to be removed from "home" to the parochial infirmary wherein they could be skilfully treated and nursed. Dr. Wynn Westcott cited some facts which had been collected by a friend of his from a neighbouring Poor-law institution. All those inmates who were above 69 years of age had been interrogated as to whether they would, if offered a 5*s.* weekly grant, accept this and take their discharge or prefer to continue as now in the institution. Of 161 men asked, 30 said that they would under the above conditions take their discharge; of 208 women 35 said that they would prefer to live outside. A liberal discount must be made from these figures, as the friends or relatives might decline to accept the responsibility for the care of these 65 would-be outdoor pensioners; nevertheless, many of those who are being well looked after at present would strive to seek their freedom and in so doing would probably run very great risks of succumbing to neglect. The events of next year will probe the coroner's fear.

NOTIFICATION AND ISOLATION OF SCARLET FEVER.

IT is impossible to avoid some disappointment at the fact that notwithstanding notification and a constantly increasing proportion of isolated to notified cases of scarlet fever, the prevalence of this disease, judged by the number of occurring cases, shows practically no decline, even in those towns where notification and hospital isolation are most thoroughly carried out. It appears from the last report of the Statistical Committee of the Metropolitan Asylums Board that during last year 25,925 cases of scarlet fever were notified in London, of which no less than 89·4 per cent. were admitted for treatment in the Board's isolation hospitals. This number of notified cases exceeded those returned in any year since 1893 when 36,901 cases were notified, only 39·7 per cent. of which were admitted to hospital; while the percentage of hospital admissions to notifications has almost steadily increased from 42·8 in 1890 to 89·4 in 1907, which exceeded the percentage in any previous year. The figures for Manchester in Dr. J. Niven's report for 1907 (noticed in THE LANCET of Oct. 10th) also fail to show a satisfactory decrease of the prevalence of scarlet fever in that city, notwithstanding the large proportion of isolated to notified cases. During last year 2732 cases of scarlet fever were notified in Manchester, considerably exceeding the number in any of the ten preceding years, except 1906, when the number was 3075. The percentage of notified cases in Manchester isolated in hospital was 65·0 in 1907, and appears to have somewhat steadily declined during the last five years from 83·4 in 1903; in 1892 and 1893, however, the percentage of isolated cases did not exceed 58·5 and 58·6 respectively. Thus neither in London nor in Manchester do notification and isolation of cases of scarlet fever appear to have fulfilled the reasonable expectation of a decided decrease in the prevalence of this disease. The marked decline in the mortality from scarlet fever is proved by the fact that while the annual death-rate from this disease in England and Wales in the ten years 1861–70 was equal to 971 per 1,000,000 persons living, it has not exceeded 116 per 1,000,000 during the ten years 1898–1907; in London and in Manchester the mortality from scarlet fever has special sense are to be avoided. Von Bergmann entered the cranium from in front, close over and to the inner side of the frontal eminence, and inserted the hollow needle through the frontal lobe of the brain backwards and keeping to the inner side. Keen punctured the lateral ventricle from the side in the following manner. The cranium was opened 3 centimetres behind and 3 centimetres above the external auditory meatus—that is, 3 centimetres above Reid's base line, which is drawn from the lower border of the orbit through the middle of the meatus. The needle is inserted in the direction of an imaginary point 6 centimetres vertically above the external auditory meatus of the other side and through the second temporal convolution. From 4½ to 5 centimetres deep lies the lateral ventricle of the brain in the course or at the beginning of the descending cornu. Keen performed the operation of puncturing, draining, and irrigating the lateral ventricles with satisfactory results. Mayo Robson also recommends puncturing the ventricles from the side, but through the first temporal convolution.

As do Kocher, Neisser, and Pollack, I recommend puncturing the ventricle from above, through the frontal bone about 2 centimetres from the central line and 3 centimetres from the precentral fissure. The hollow needle must be pushed downwards and backwards. You strike the ventricle at a depth of from 5 to 6 centimetres. The ventricles can also be drained very well from above. Care must be taken not to insert the drainage-tube too deeply into the ventricle, so as to avoid injuring the opposite wall. This can easily be avoided by fitting a ring or shield to the tube.

As it offers so little danger of infection, subcutaneous drainage is most advantageous. For a really efficacious draining of the ventricle Payr recommends transplanting living pieces of human arteries, taken, for instance, from the arteria radialis or brachialis, into the lateral ventricle in such a way that the other end becomes grafted in the sinus longitudinalis. In this way the serous fluid from the ventricle is carried away by the blood. This operation can naturally only be successful when performed in the best way in every respect. From what we know to-day of transplantation it may reasonably be expected that living pieces of artery can be thus grafted into the ventricle and sinus longitudinalis.

Finally, the ventricle may also be punctured from behind, from the occipital lobe. According to von Beck the tip of the posterior cornu is met with at a depth of about 3 centimetres, if the cranium is opened 4 centimetres over the protuberantia externa and 3 centimetres to the side of the central line of the skull, in which case the needle is inserted in a forward and slightly upward direction.

Leipsic.

NOTES ON

679 OPERATIONS PERFORMED UNDER SPINAL ANÆSTHESIA (COCAINE OR STOVAINE) BY TUFFIER'S METHOD.

BY DR. SABADINI,
SURGEON TO THE CIVIL HOSPITAL, ALGIERS.

(*Translated for the Author by* ALFRED S. GUBB, M.D. PARIS.)

IN August and September, 1903, even before Dr. Fourneau read his paper on *stovaine* at the Académie des Sciences (February, 1904) and Chaput his communication to the Société de Biologie (May 2nd, 1904) I found, in the course of a visit to various hospitals of Paris, the provinces, and abroad, that the majority of surgeons were ignorant of this method of inducing surgical anæsthesia, while some indeed frankly stated their view that the method was absolutely unphysiological and dangerous. Of the latter it was evident that none of them had ever tried it and their statements were obviously based merely on impressions derived from the medical journals. Yet the remarkable publications of Leonard Corning and of Tuffier (1889), the inventor of the method, and of his pupils, Cadol and Nicolendorff, the contributions by Nicoletti of Naples, Professor Bier of Kiel, and his assistant Eden, and those of Schiani and Durante of Italy, had peremptorily established the fact that the introduction of cocaine into the spinal column produced widespread anæsthesia *without circulatory or respiratory disturbance and that cocaine determined no grave changes in contact with the nerve elements.* Since that time numerous articles have appeared in the various medical journals in France and elsewhere by surgeons who have practised this method of anæsthetisation with satisfaction to themselves and benefit to their patients.

Why, then, this ostracism or this indifference in regard to a method which had been fully tried? In part no doubt to the attacks of Réclus and Laborde, the latter, by the way, being a physiologist and not a clinician, but neither attack was supported by any weighty reasons. Legueu's two mishaps and Broca's fatality, neither of which could fairly be attributed to the cocaine, seem to have made surgeons hesitate. My object in publishing my statistics of spinal cocainisation is to show that lumbar anæsthesia is in no wise dangerous and that the accusations which have been levelled at the method by its detractors are without foundation.

SPINAL COCAINISATION.

It was in July, 1900, that I for the first time saw Tuffier practise spinal anæsthetisation at the Lariboisière Hospital for the removal of a uterine fibroid. The anæsthesia was complete and was not attended by any untoward incident. On my return to Algiers I at once put the method into practice, so that my experience dates from August, 1900.

I may state at once that I have never imposed spinal cocainisation on my patients. Having proposed it, in the event of refusal I gave chloroform or other general anæsthetic according to circumstances. The cases comprise operations of every degree of severity: resection of ribs, hydatid cysts of the liver and peritoneum, strangulated hernia, abscess of the liver, eventration, incised wounds of the abdomen and contained viscera, on the anus and rectum, with a very large proportion of operations on the genital organs of both male and female, and on the limbs.

Age.—The patients' ages varied from 15 to 93 years and age *per se* is not regarded as a contra-indication.

Nature of the operation.—The operations performed under spinal anæsthesia were always low down—i.e., below the level of the umbilicus, anæsthesia extending upwards *as a general rule* to within two fingers' breadth below the mammæ.[1] Yet I have removed three mammary cancers by this method and done one resection of the elbow for tuberculosis in a girl, aged 18 years. The dose in these four cases was 3 centigrammes for the first three and 4 centigrammes for the fourth. In order to insure diffusion of the cocaine I was careful to keep the patient in Trendelenburg's position for ten minutes after the injection but anæsthesia was not complete, and I was fain to have recourse to chloroform, so that I have not repeated the experiment. In empyema I usually resect the tenth rib and in these instances the anæsthesia was sufficient.

By employing spinal anæsthesia only in persons who willingly submit thereto one reduces the number of failures; these in my experience amounted to about 11 per cent. It is with cocaine as it is with ether and chloroform, by which I mean that there is such a thing as idiosyncrasy or rather that the anæsthetic dose varies according to the individual. I am inclined to think that if we adopted in respect of cocaine the procedure which Chaput has adopted for stovaine—that is to say, if a further injection of 1 or 2 centigrammes were made—complete anæsthesia might be obtained in every instance. It was noted that most resistance was shown by alcoholic and nervous subjects. I recall the case of a nervous woman with a double pyosalpinx who only reluctantly agreed to the injection and obliged me in the middle of the operation to call chloroform to *my* aid. Yet this very patient confided to her neighbour that as a matter of fact she did not feel anything but that the bandage having fallen from her eyes she saw her belly open and began to scream. This is not infrequently the case; the patient feels no pain but owing to a lack of surveillance they see what is going on and get alarmed, or it may be they feel when tissues are being dragged upon as during the removal of large uterine fibroids.

Immediate effects.—By this I mean the subjective phenomena between the fifth and the fifteenth minute after injection such as pallor, sweating, nausea, vomiting, and occasionally *but rarely* marked apprehension; and, secondly, epileptoid tremor of the lower limbs and fatal syncope.

---

[1] I have invariably employed Poulleno's solution 2 centigrammes per bulb.

shallow. One-twentieth of a grain of strychnine hypodermically and brandy were given, and artificial respiration was performed. Improvement took place and the operation was completed. Four days later an oval purplish vesicle, of about the size of half a crown, appeared on the sole of the left foot behind the little toe, and the skin beneath became purple. There was neither pain nor inflammatory reaction. Two days later a similar patch appeared on the outer part of the heel. In each case the subjacent skin became black and necrotic and separated slowly as a slough. On May 22nd healing was far enough advanced for the sores to be grafted which was done under local cocaine anæsthesia with good result. The Thiersch grafts applied to the leg were perfectly successful. Goldmann[1] has reported a case of gangrene of the skin of both heels following a spinal injection of two cubic centimetres of novocaine-suprarenin solution. The patient was 52 years of age and healthy, except for a moderate degree of arteriosclerosis. The injection was followed by severe pains in the neck, back, upper limbs, and especially in the heels. Dr. Morton suggests that the adrenalin may have been responsible for the gangrene which was obviously a trophic change. It will be interesting to note whether cases of gangrene occur after the spinal injection of the stovaine-glucose solution which is recommended by Mr. A. E. J. Barker[2] and so far has given excellent results.

THE INSPECTION OF SCHOOL CHILDREN BY COUNTY MEDICAL OFFICERS OF HEALTH.

IN our issue of Oct. 17th we commented under the above heading upon the situation which has arisen in Herefordshire as to the appointment of a county medical officer of health, part of whose duties would be the inspection of all the school children in the county. We pointed out that the council expected its county medical officer to pay for any assistance which he might require out of his own pocket. We now learn that the salary offered was £500 a year, out of which an assistant would certainly have to be paid—there are, we may add, some 16,000 children in the county—and other expenses, such as travelling expenses, would have to be considered. Altogether it is probable that the £500 a year would be reduced to something over £200 by the time when all expenses had been paid. Mr. Herbert Jones, as we said before, rightly demurred to the proposals of the committee as to the inspection of school children and the suggestion that the county medical officer should pay for any assistant out of his own pocket. He therefore withdrew his application for the post. At a meeting of the Herefordshire County Council, held on Oct. 10th, we see that it was decided that the education committee should select three other candidates to appear before it from whom an appointment might be made. We have before us a letter dated Oct. 16th in which the clerk of the Herefordshire County Council informs one of the candidates that he (the clerk) has been "directed to inquire whether your application may still be considered as before the committee." This letter would appear to show that the education committee is still in hopes of obtaining a medical officer on the terms which Mr. Herbert Jones has rejected. We cannot think that £500 per annum is an adequate salary if out of that £500 about half must be deducted for assistance; but, as we said in our leading article last week, the proposal that the county medical officer of health should have most of his time taken up by the inspection of school children is one which cannot be commended on general sanitary grounds. The Herefordshire county council might take example by the Norfolk education committee which is about to appoint two medical men for the medical inspection of children under the supervision of the county medical officer of health. These two gentlemen will each get £250 per annum and the necessary travelling expenses.

THE MODERN BLOATER.

THE bloater is excellent food and probably represents a nutritive value, having regard to its cheap price, greater than all the other animal foods. Not only, however, is the herring decidedly nutritious but in the cured form it is also tasty and appetising. It is to be feared, however, that modern bloaters, and more particularly the specimens sold in London, are often robbed of their attractive qualities by the adoption of a process of curing which is an ineffectual imitation of the better classical method. Possibly a "short cut" to the obtaining of a bloater from the fresh herring consists simply of a process of pickling the fish in, or brushing the surfaces with, a curing "essence" composed of tar or smoke oils. It should not be forgotten that curing by smoke not only preserves the fish but adds to it a condiment which aids the appetite and does no injury to the organism. The treatment, therefore, with solutions of antiseptics cannot be regarded dietetically in the same light as can the curing process. It is not unlikely, also, that borax and other antiseptics are used in order that the preserving process may produce what is called a "mild cured" article. In this way it is not unlikely that stale or even worse herrings are manipulated which might obviously be a source of danger to health. The result is that the modern bloater is often, as a correspondent has rightly pointed out, sodden, tasteless, unpleasing, or even only just eatable, whereas the bloater of previous times was attractive in appearance, the flesh being firm and sound yet tender and possessing an agreeable flavour. The same remarks apply to the kippered herring. Surely modern methods which detract from the pleasing or the important æsthetic qualities of a cheap and wholesome food need strongly to be condemned, especially in these days when we hear so much of the sufferings experienced by the starving unemployed.

PUNCTURE OF THE BRAIN.

ELSEWHERE in this issue we publish an article by Professor H. Tillmanns of Leipsic on a very important subject, puncture of the brain. The operation is as old as the time of Hippocrates, though it would be rash to believe that it was employed by the Father of Medicine himself, for much that is ascribed to Hippocrates is really due merely to his school. In the literature of the centuries which have passed since these early days of medicine references may be found here and there to the practice of puncture of the skull, but it is only within recent years that any systematic advance has been made, and even now many surgeons look askance at the operation. Antiseptic surgery has robbed the operation of the dangers which it once possessed and when practised with care the risk is extremely small. As Professor Tillmanns points out, puncture of the brain can be employed both for diagnostic and for therapeutic purposes. For diagnosis a puncture may be employed when there are signs of pressure on the brain or when an accumulation of blood, pus, or other fluid is suspected in the substance of the brain or in its ventricles. When the diagnostic puncture affords definite information it will be immediately followed by an operation for the removal of the disease. For purposes of treatment puncture of the brain is also of no small value. It can be used for cases where fluid has collected in the ventricles, and it has also been employed for the injection of liquids, such as tetanus antitoxin, into the cranial cavity, though this centigrammes. In one case 15 centigrammes were injected by error, the patient being a chronic inebriate with congested lungs who was brought in with double malleolar fracture and who refused chloroform. He presented very disquieting symptoms: intense dyspnœa, cyanosis, hiccough, thready pulse, headache, and vomiting with faintness. Dry-cupping to the chest, injections of caffeine, and inhalations of oxygen overcame the symptoms in about a quarter of an hour. He complained of numbness of the legs for two days after the accident. In five instances the anæsthesia was incomplete. Retention of urine was noted in 16 cases, lasting from 18 hours to eight days, and in one instance for two months. In the last-named case the patient also suffered from obstinate constipation which was only overcome 40 days after the operation. Dysuria was complained of five times and lasted for from 24 hours to 10 days. In one instance there was anuria for 24 hours following the injection of ten centigrammes of stovaine for an operation on hæmorrhoids.

---

[1] Zentralblatt fur Chirurgie, 1907, No. 2.

[2] THE LANCET, Sept. 5th, 1908, p. 710.

The duration of the anæsthesia was from 10 to 100 minutes. This is usually proportional to the amount injected but not invariably so, and in some cases the injection of only 5 centigrammes was followed by prolonged anæsthesia. Perfect anæsthesia in alcoholic and nervous subjects cannot be relied upon with a less dose than 10 centigrammes.

In 11 cases slight headache was complained of and in seven it was severe. Vomiting was only noted on eight occasions *during* the operation and six times *after* the operation, either later in the day or on the following day. Rachialgia was complained of once and slight rise of temperature 12 times.

On the whole, the advantages appear to be in favour of spinal stovainisation and I may conclude: 1. That spinal stovainisation is an excellent mode of inducing anæsthesia which may be employed without danger from 15 years until an advanced age. 2. The dose of stovaine is from 5 to 10 centigrammes; this affords good anæsthesia which may last one and a half hours. 3. The constitutional disturbances are slight and never interfere with the performance of the surgeon's duties and they seem to be less frequent with stovaine than with cocaine.

The only serious drawback is the comparative frequency of urinary retention (44 out of 146 cases), lasting from one to several days. This drawback, which only exceptionally occurs when cocaine is employed, may not improbably lead me ultimately to give the preference to cocaine in the absence of the contra-indications mentioned above.

Algiers.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

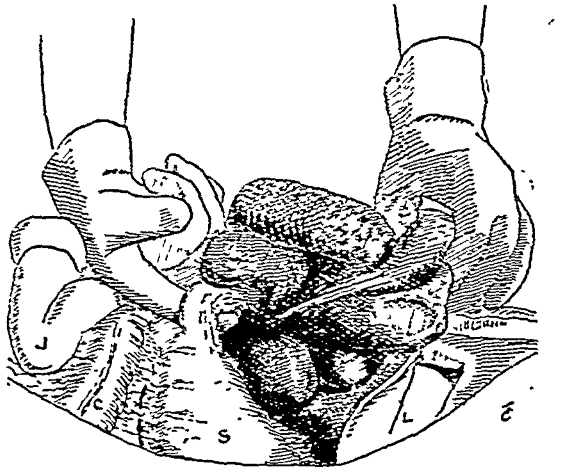
NOTE ON A CASE OF HERNIA THROUGH THE FORAMEN OF WINSLOW.

By T. CARWARDINE, M.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE ROYAL INFIRMARY, BRISTOL.

HERNIA through the foramen of Winslow is so rare that the accompanying details of a case may be of interest. An engineer, aged 44 years, whilst using the telephone was suddenly seized with severe colicky pains which made him double up. He was not at first sick but had slight nausea, and the pain continued on and off afterwards and prevented sleep. On the next morning he was sick several times; on the morning of admission, two days after the onset, he brought up black vomit, so resembling ink in character and smell as to cause inquiries to be made as to whether any ink had been added to the vomit. The patient was dusky, with cold extremities; the pulse was feeble and 124; the temperature was 97° F. The abdomen was distended but not tense except in the epigastrium where there were resistance and impairment of resonance corresponding with the position of the lesser sac of peritoneum. Constipation had been absolute for the last 24 hours.

An immediate operation was performed. The patient was almost pulseless. The bowel, black and lustreless, was discovered on tearing through the gastro-hepatic omentum. A portion of the bowel was reduced, but an uncertain vascular band seemed to prevent reduction of the remainder; and as the patient's condition was bad drainage-tubes were put into the involved gut, the patient dying three hours afterwards.



Hernia through the foramen of Winslow. (From a photograph by Professor I. Walker Hall.) S, Stomach. L, Liver. C, Transverse colon. J, Jejunum.

Professor I. Walker Hall kindly furnished the following notes of the post-mortem examination: "At the autopsy it appeared that about 24 feet of the lower end of the ileum were present in the lesser sac. The entering portion had passed over the ascending and right part of the transverse colon, and then into the lesser sac. From the point of entry the lower part of the ileum dragged on the ileo-cæcal valve, the mesentery being twisted so as to form a distinct, sharp edge, simulating a band containing blood-vessels."

The illustration was drawn from a photograph kindly furnished by Professor Walker Hall.

Clifton.

NOTES ON A CASE OF ACUTE GOITRE.

By SIDNEY J. O. DICKINS, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

THE patient was a girl, aged 16 years. Her mother was dead but her father was alive and well. She had one brother alive who was healthy, but her three sisters were goitrous, one subsequently coming for treatment and recovering in three weeks, after taking syrup of iodide of iron and iodide of potassium and painting the gland with tincture of iodine. The patient, who was a fairly healthy looking girl, appeared to be well nourished but was a little anæmic, and she had a simple parenchymatous goitre. There had been no catamenia and slight exophthalmos was present. She had walked two miles to the surgery. She complained of difficulty in swallowing and in breathing. The tonsils were slightly inflamed. The left lobe of the thyroid was of about the size of a duck's egg and it extended behind the trachea, and was pressed down firmly upon the sternum during the act of swallowing and during inspiration. The gland was rather hard and could not be separated from the trachea. The patient was given half a drachm of syrup of iodide of iron and three grains of iodide of potassium three times a day, the gland being painted every night and morning with tincture of iodine. I was called up early on the following morning to see the patient who experienced considerable difficulty in breathing and in swallowing. There was an increase of stridor and the breathing was most comfortable when the patient was sitting up in a chair. There was no elevation of temperature and the pulse rate was 60 and of fair volume and tension. I ordered inhalations of steam, hot fomentations to be applied to the throat, and gave a gargle of chlorate of potassium and carbolic acid. The patient was more comfortable during the day. I was called up again on the next night, the messenger expressing the opinion that the patient was dying. I took with me effect of the hope aroused in patients under sentence of death. But this was only temporary. Dr. Weinstein sarcastically concludes: "There is no need to import placebos from Edinburgh. We have plenty on this continent." In a paper read at the Congress of the International Surgical Society and published recently by us[3] Mr. Henry Morris exhaustively discussed the trypsin treatment of cancer and came to an adverse conclusion.

EGYPTIAN VITAL STATISTICS FOR 1907.

IN an unsigned report issued with the usual statistical return of the Egyptian Public Health Department for the week ending Sept. 16th, 1908, we are supplied with an abstract of the demographical results of 1907. The native population on July 1st, 1907, exclusive of nomads, amounted to 11,038,112, showing an increase of 223,544, or about 2 per cent., on that of the preceding 12 months. These figures may be accepted as fairly exact, but the foreign population (which is returned as 112,447, the same as in 1907) can only be regarded as approximately correct because under the capitulations foreigners cannot be compelled to register births. This grave defect has often been mentioned in our columns and elsewhere, but apparently there must be difficulties in the way of its removal, which for some unaccountable reason are deemed to be insurmountable. The native births during the 12 months were at the rate of 43·7 per 1000; during the preceding year the birth-rate was 44·4 per 1000. 1334 foreign births came to the knowledge of the Public Health Department, but no rate can be furnished because, as already said, "the births of foreigners .... are not all notified." The native death-rate for 1907 was 27·0 per 1000 against 24·1 in 1906. The deaths in the foreign population took place at the rate of 23·0 per 1000; during 1906 it was 19·8 per 1000. The number of vaccinations performed during the twelvemonth was 456,285 with 3166 failures. There were also 4453 revaccinations, among which 714 were unsuccessful. The native births numbering 482,407 were in excess of the number of vaccinations by 26,122, but this discrepancy was no doubt due to premature infantile mortality. With regard to vaccination there is apparently no diffentiation in this return between natives and foreigners. The total number of nomads, or Bedouins as they are called, was 602,139. They are distributed all over Egypt and in many cases have long ceased to be wanderers.

SPENGLER'S TREATMENT OF TUBERCULOSIS.

WE have already alluded[1] to the results which are said to have been obtained in cases of tuberculosis from the use of a form of inoculation devised by Dr. Spengler of Davos. We have now received a reprint of an article by him,[2] in which an account is given of the theoretical basis on which his treatment is founded. It would seem that in attempting the cure of disease by means of the separated serum of the blood we have thus far been throwing away the substance for the shadow, since, if Dr. Spengler be right, it is in the red corpuscles of the blood that the immunising substances are formed and mainly stored, only a small proportion overflowing into the serum. Thus, according to his experience, there may be in the dissolved erythrocytes as much as one million times the quantity of the immune body which is contained in the serum; and this rule applies both to agglutinating and precipitating bodies and to antitoxic and bactericidal substances. The last two are, of course, the most important. Dr. Spengler states that the antitoxic body may be recognisable in a dilution of 1 in 100,000,000,000 of the blood of an immune animal. He admits that action in such a dilution is something apart from ordinary chemical action and speaks of an "atomic dissociation" which takes place, liberating "specific electrons." He has prepared the immune body from animals and advises its use as a remedy for human disease in the form of hypodermic injections; it can also be rubbed into the skin. It is not an albuminous substance. It is polyvalent, acting against pyogenic bacteria as well as against tubercle bacilli. It is procurable commercially under the name of "J. K." (Immun Körper). The theory propounded by Dr. Spengler is somewhat startling but it should not be difficult to verify his views as to the preponderance of immune bodies in the erythrocytes. If this be confirmed, then treatment by his vaccine will be supported by independent evidence and should receive prompt trial in this and other countries.

THE annual meeting of the Association of Public Vaccinators of England and Wales will be held at the Hotel Cecil, London, on Friday, Oct. 30th, when the chair will be taken by the President (Dr. A. Drury of Halifax) at 3 P.M. After the transaction of business a paper will be read by Dr. A. E. Cope (London), entitled, "Small-pox: What it was before the Introduction of Vaccination; and the Future of Small-pox, What is it to be?" The annual dinner will take place at the same hotel at 6.30 P.M. All public vaccinators, whether members of the association or not, are cordially invited and are asked to communicate early their intention to be present to the secretary of the association, Mr. Charles Greenwood, 1, Mitre-court-buildings, Temple, London, E.C.

THE opening lecture of the winter session of the Mount Vernon Hospital Post-graduate Course will be given by Sir James Barr on Oct. 28th, at 5 P.M., at the central out-patient department of the hospital, 7, Fitzroy-square, London, W. The subject of the lecture, to which qualified medical practitioners are invited, will be "Mitral Stenosis."

MR. William Knight Treves, F.R.C.S. Eng., died at his residence in Margate, on Oct. 14th, aged 65 years. Mr. Treves, who was a brother of Sir Frederick Treves, qualified as F.R.C.S. Eng. in 1870 and at the time of his death was consulting surgeon to the Royal Sea Bathing Hospital at Margate.

WE regret to announce the death of M. Paul Berger, the great French surgical authority on fractures and dislocations, which occurred on Oct. 17th. Pressure on our space forbids an extended notice of his career in this issue, but we hope to publish one later.

A TELEGRAM from the Governor of Mauritius received at the Colonial Office on Oct. 16th states that for the week ending Oct. 15th there were 13 cases of plague and 9 deaths from the disease.

THE first scientific meeting of the Zoological Society of London for the session 1908-09 will be held in the society's rooms at 3, Hanover-square, W., on Tuesday, Nov. 3rd, at 8.30 P.M.

UNIVERSITY COLLEGE, LONDON.—A course of eight lectures on Certain Fundamental Problems in Physiology Common to Animals and Plants is being given by Dr. W. M. Bayliss on Wednesdays, at 5 P.M. The lectures will be devoted mainly to the permeability of cells and membranes and phenomena connected therewith, such as plasmolysis, secretion, nature of the nerve-impulse, &c. The lectures are open to all students of the University of London, also to qualified medical men and to such other persons as are specially admitted.

[3] Ibid., Oct. 3rd, 1908, p. 997.

[1] THE LANCET, March 21st, 1908, p. 893.

[2] Deutsche Medicinische Wochenschrift. 1908, No. 38.

distension of the fœtal bladder without stenosis of the urethra and he pointed out that although the view that a fœtus could empty its bladder into the closed amniotic sac was commonly held, no one had brought forward any evidence that this was possible, and it appeared to be very unlikely, although the cases where great hypertrophy of the bladder wall existed, as reported by Dr. Spicer, seem to show that in certain circumstances it might be possible.

Mr. DORAN and Dr. CUTHBERT LOCKYER communicated a paper on two cases of Uterine Fibroid showing Peritheliomatous Changes. The first patient was a 5-para, aged 49 years. A cystic uterine fibroid over 14 pounds in weight was removed by supravaginal hysterectomy, with an ovary the seat of fibroma. The opposite Fallopian tube and ovary were not removed. The solid part of the uterine tumour showed on microscopical examination all the characters of malignant perithelioma. Four and a half years after operation the patient had become very corpulent and there was no evidence of recurrence. The second patient was a 2-para, aged 36 years. A cystic uterine fibroid 2½ pounds in weight, invading the left broad ligament and sigmoid mesocolon, was removed by supravaginal hysterectomy, as total removal of the uterus appeared impracticable. There were marked changes in the left Fallopian tube and ovary and deposit in the parametrium of doubtful nature. The uterine tumour and the growths in the left tube, ovary, and parametrium showed on microscopic examination all the characters of malignant perithelioma. Speedy recurrence was expected, yet two years and seven months after the operation the patient was living and in good health. The stump of the cervix had become very small and the deposit in the left parametrium had disappeared. These cases showed the extreme importance of careful observation of all patients on whom hysterectomy for the removal of fibroid tumours had been performed.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

The British Pharmacopœia: Its Scope and Object.

THE first meeting of the session of this section was held on Oct. 6th, Dr. T. E. BURTON BROWN, the President, being in the chair.

Dr. NESTOR TIRARD read an address on the British Pharmacopœia: Its Scope and Object. After briefly mentioning some of the criticisms upon the present Pharmacopœia and indicating that in many instances they betrayed a lack of appreciation of its scope and object, Dr. Tirard quoted from the Medical Act of 1858 the terms under which the General Medical Council is directed to prepare the Pharmacopœia. In the Medical Act the original scope and object are accurately defined, but many factors, besides the changes of therapeutic practice, have served to widen the scope. In 1898 by some modifications of strength of galenical preparations greater freedom of prescribing was encouraged and the work of students and of medical men was diminished. Since that date the Indian and Colonial Addendum provided for the requirements of those practising in India and the colonies, drugs of local reputation and modifications requisite owing to climatic conditions being introduced. Further changes would be necessary to secure greater uniformity in the pharmacopœias of different nations and reference was made to the international agreement which had been signed with this object. Turning next to the steps which were being taken in view of a forthcoming new issue of the Pharmacopœia, Dr. Tirard indicated that great progress had already been made with many points involving prolonged researches; these had been undertaken very shortly after the publication of 1898. The Pharmaceutical Societies of Great Britain and of Ireland had been invited to appoint representatives to confer with members of the Pharmacopœia Committee of the General Medical Council, and numerous subjects requiring investigation had been submitted to various experts in pharmacy and pharmaceutical chemistry. Particular reference was made to the researches made by Professor Greenish on solubilities and ash yields, and to the report by Professor Dunstan on the best methods of testing for arsenic and the limits of that impurity in medicinal substances. Mention was made of the steps taken to ascertain what omissions, additions, and alterations in the Pharmacopœia were desired by medical men and by pharmacists, and of the reports received from the different medical authorities, from the Therapeutic Committee of the British Medical Association, from a collation of recent prescriptions, and from a committee of wholesale druggists. While the details of most of these were at present confidential, the report of the Therapeutic Committee indicated some points which might call for discussion. Mention was made of the suggested elimination of all substances devoid of action, which could be determined by physiological experiment or by therapeutic observation. The difficulties likely to be entailed by the introduction of sera or of the physiological standardisation of drugs were also referred to, since these appeared to involve the creation of special State laboratories and the substitution of an official guarantee in place of personal responsibility. In conclusion, Dr. Tirard said that in view of the number and diversity of the suggestions received, it would be impossible to act upon them all, but that he hoped the new Pharmacopœia would show that much had been done by good intentions and by mutual concessions.

Dr. C. O. HAWTHORNE pointed out the danger of regarding the Pharmacopœia as an official treatise upon drugs. It was no part of the duties of the Pharmacopœia to recommend particular drugs, or particular combinations of drugs. It was its sole duty to determine a standard of purity. That a drug was used entitled that drug to admission into the Pharmacopœia, however doubtful its merits might be. Nor should the Pharmacopœia be regarded as a text-book. It should be recognised that it was both unnecessary and impossible for a student to attempt to commit its contents to memory.

Mr. H. WIPPELL GADD referred to difficulties which had arisen in courts of law recently. It had been held that certain drugs must be dispensed in Pharmacopœial strength.

OPHTHALMOLOGICAL SOCIETY.

Dipterous Larva in the Anterior Chamber.—Six Generations of Piebalds.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 15th, Mr. R. MARCUS GUNN, the President, being in the chair.

Dr. FRANK G. THOMAS and Mr. J. HERBERT PARSONS communicated a paper on a case of Dipterous Larva in the Anterior Chamber. The case was that of a male, aged two and three-quarter years, who was seen on March 18th of this year. Three and a half weeks previously the left eye was noticed to be red and photophobic and the child seemed occasionally to be in pain. There was no history of injury or illness, nor any symptoms suggestive of intestinal "worms." On examination under an anæsthetic the eye showed slight ciliary injection, the cornea was clear, the anterior chamber was deepened, and the aqueous faintly turbid; the iris was discoloured and pattern-fogged and the pupil was irregular and filled with pigmented lymph. Lying on the iris was a long cylindrical body resembling a small worm, its head being in the lower and outer quadrant and its tail in the angle of the anterior chamber at the upper and inner quadrant. The body consisted of eight segments and measured 12 or 13 millimetres, was of greyish-yellow colour, and showed no movements. With a binocular loupe a fine covering of grey material could be made out enveloping it and reflected on to the iris. The tension was −1 and the eye was blind. Enucleation was performed on the same day. The eye was hardened in formol and sections were made at right angles to the foreign body. The anterior chamber contained exudate in front of the iris, tying down the cylindrical mass to it; the lens was somewhat shrunken and the vitreous was also shrunken and contained a coagulum. The retina was detached with sub-retinal coagulum. Microscopically, the cornea was found to be slightly infiltrated at the periphery. The anterior chamber was deep and contained homogeneous coagulum with multitudes of leucocytes. The angles were widely open and the region of the canal of Schlemm was densely packed with leucocytes. Lying on the surface of the iris was a circular body bounded by hyaline membrane, which was clearly an animal parasite. The iris, ciliary body, and retina were densely infiltrated with leucocytes. The lens was distorted, showing cataractous changes, and was covered by a fibrinous coagulum, the latter being also seen covering the ciliary body. The choroid was *in situ* and was

Extract of Meat Company farmed in 1868 some 28,494 acres of land, and the total herd of horned cattle reared on this area was 12,000; in 1878 the number of acres was 37,961 and the number of cattle 19,036; in 1888 the number of acres was 126,984 and of cattle 36,685; in 1898 the pasture land comprised 254,133 acres and the cattle numbered 66,435 head; and this year (1908) the acreage is no less than 1,302,386 and the number of cattle 224,406. That is to say, that at present this company possesses one and a third millions of acres of grass lands and nearly a quarter of a million of cattle. Striking as the figures may be as illustrating the enormous expansion of the cattle-rearing industry, they become still more impressive when regard is had to the fact that the cattle are no longer, as in Liebig's day, and according to his own words, "half-wild animals," but are bred from the choicest pedigree stock taken from the farms of our best English breeders. Drafts of Hereford bulls of the type shown in Fig. 1 and heifers and Aberdeen Angus, all from prize pedigree stock, are at intervals sent out not merely to perpetuate the herds but to improve the race and so to maintain such a superior class of beast as to produce a corresponding quality in the food product. Moreover, the Argentine and Uruguay authorities insist upon certain strict precautions being observed before the pedigree animals are admitted into the country. One certificate, for instance, is required from the home farm stating that the animals and the herd from which they came are free from disease and another to the effect that at the port of shipment the animals were sound. A further document is required from the Board of Agriculture that in the land whence they came there is a freedom from foot-and-mouth disease and so forth. On arrival the animals have to undergo government veterinary examination and a quarantine of 40 days, towards the end of which the tuberculin test is applied. The animals are only allowed to proceed to their destination when these tests have been proved to be satisfactory, failing which the beasts are killed without any compensation to the owners. As a rule, importers take the precaution of having the tuberculin test applied to the animal before it is shipped. It must be admitted that these stringent rules, made, as they are, in the interests of the health and sanitary conditions of the animals, are admirable and calculated to prevent the possibility of bovine disease being introduced into the country from without.

MODERN CATTLE FARMING AND ITS MAGNITUDE.

It is difficult to convey an adequate sense of the magnitude of the cattle farms situated upon the Liebig Company's property in the Argentine, in Uruguay, and in Paraguay.

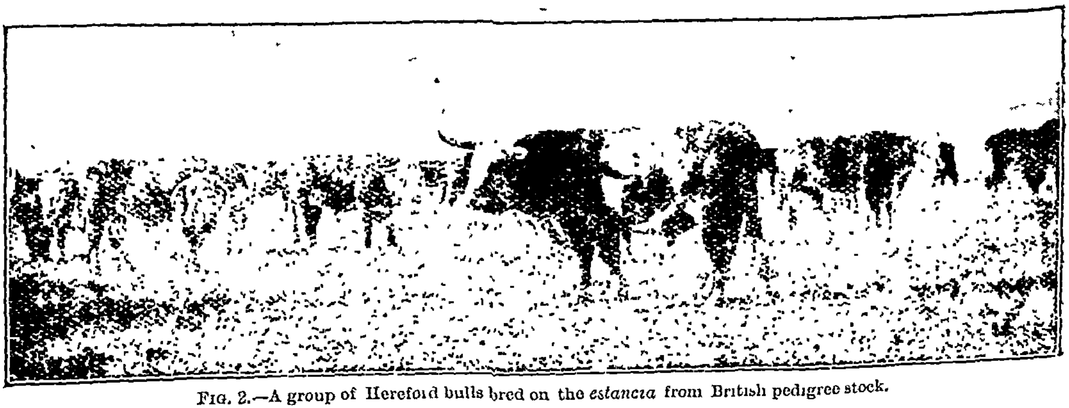

FIG. 2.—A group of Hereford bulls bred on the *estancia* from British pedigree stock.

Even a rapid round of all the *estancias*, without spending more than a day and a night at each, would occupy the best part of three months. And the traveller would encounter over the thousands of miles covered a vast ocean of grass ever being replenished by a congenial climate, studded by innumerable herds of cattle, each perhaps comprising from 2000 to 4000 head, and after some days he would probably get satiated with the sight of so many cattle, albeit they are splendid beasts the sires of which are English pedigree-bred (Fig. 2). He would appreciate the curiously exhilarating and pure air; the sense of real fatigue comes but rarely in spite of hard travelling. He would admire the marvellously healthy-looking condition and cleanly and picturesque appearance of the cattle, due to careful breeding and selection of stock, and above all to the fact that every moment of their life day and night is spent in the open air. The whole camp is, in short, one stupendous example of the open-air life. It not only supplies abundance of good pasture and water but it provides also a continual supply of fresh pure air which effectually guards the cattle from those diseases to which they are prone. Nothing could be more striking in favour of open-air treatment than the immunity from tuberculous disease which cattle share when their life is lived entirely in the open. There is no such thing as a stall-fed beast on the great grassy camps of the *estancia* and the tubercle bacillus finds such an environment uncongenial to its growth and development. As the towns or cities are approached so does the environment grow favourable for infection and the figures giving the returns of cases of tuberculosis amongst cattle admitted at the freezing factories (*frigorificos*) in the towns, as against the returns of those killed at the preserving factories (*saladeros*) situated up country and in convenient proximity to the camp, are interesting in this connexion.

TUBERCULOSIS FIGURES (CATTLE) IN THE ARGENTINE 1903-1907 *INCLUSIVE.*

	Number of cattle.	Number affected with tuberculosis.	Percentage tuberculosis.
1903.			
Freezing establishment (frigorificos) ...	230,095	646	0·29
Preserving factories (saladeros)	202,082	5	0·002
1904.			
Freezing establishment (frigorificos) ...	307,803	2000	0·64
Preserving factories (saladeros)	235,735	14	0·005
1905.			
Freezing establishment (frigorificos) ...	520,166	7760	1·49
Preserving factories (saladeros)	330,534	44	0·01
1906.			
Freezing establishment (frigorificos) ...	564,171	6212	1·10
Preserving factories (saladeros)	285,048	89	0·03
1907.			
Freezing establishment (frigorificos) ...	558,578	5604	1·00
Preserving factories (saladeros)	392,608	192	0·04

Our Commissioner was supplied with the above figures by an official at the offices of the Ministry of Agriculture with whom he had an interesting interview on this question. They show a highly favourable contrast with those recording the number of cattle affected by tuberculosis in this country. Official returns, in fact, show that at least a fourth, and probably more, of the cattle in England are affected with tuberculosis. But the experience again in this country is that immunity is most enjoyed by the breeds that are less domesticated—that is to say, by those cattle which live an outdoor life.

THE METAMORPHOSIS OF GRASS.

The vast camps furnish the arena for the metamorphosis of their prolific grasses into animal substances. For this great synthetic process the bovine machine requires nothing more than grass, water, and air, and of these the supply is south-west of the European settlement, that was to leeward having regard to the prevailing direction of the dry season wind, and about 400 yards away. So far as could be done, all cases of meningitis were isolated as early as possible, but it was a very unpopular measure with the natives and a great difficulty was the nursing and feeding of patients as there were no trained nurses or dressers in the station. Disinfection of the hospital was sufficiently easily and completely performed at the end of the epidemic by firing the grass roof which fell into the mud building. Isolation was preached to the chiefs and headmen of the infected villages, and in one or two cases they were prevailed upon to build an outlying grass hut for the reception of patients. But the objection raised, with some reason, was that the patients so isolated ran risk of attack at night from wild beasts; generally the utmost that could be done was to collect the sick together in one compound, or one part of a compound, from which the younger people were excluded so far as possible. The probable methods of spread of the epidemic were pointed out and the rudiments of sanitation instilled into their primitive minds. 3. Disinfection of infected houses with burning sulphur was carried out where possible. 4. Examination of suspicious cases of sickness among caravans. 5. Funeral customs, with the consequent intervisiting, were forbidden or restrained so far as possible. 6. House-to-house visiting on any large scale could not possibly be carried out on account of the large areas covered by the separate villages, but, so far as could be done, all cases of sickness were examined. 7. The public market was closed where considered necessary, as in Tumu, having regard to the people from infected villages who frequented it. 8. Station carriers and labourers were not taken from villages where sickness was present. 9. *Zongas* or caravanserais had been erected in many cases by the district commissioners to serve as a halting place for travelling caravans, thus avoiding the necessity of traders sleeping in native villages. 10. Dr. Horn found it advisable at the time of the Chief Commissioner's tour of the Northern Territories to suggest that owing to the prevalence of the epidemic at that time in the Lorha and Tumu districts it would be inadvisable for the chiefs or headmen of the villages to travel to these stations for the purpose of meeting the Chief Commissioner as it would in many cases entail their sleeping at infected villages on the road and so possibly spread the infection. That suggestion was acted upon and any large congregation of chiefs at Lorha and Tumu was avoided. 11. He also suggested to the Chief Commissioner while at Lorha that it would be unwise while the epidemic prevailed in the dry season to allow any gang of natives from the infected districts to be taken down country for work at the mines in Ashanti and the Colony owing to the grave risk of introducing the infection to those parts. The Chief Commissioner agreed with the suggestion and no men were sent. Dr. Horn wished also to lay stress on the fact that severe epidemics of cerebro-spinal meningitis, such as had occurred in West Africa for certainly the last three years, could not be considered apart from the grave epidemics of the same disease which had occurred so recently in many parts of Europe, including the United Kingdom. Amongst the civilised peoples of Europe every step could be taken to arrest the progress of the disease, but it must be admitted that it was at least possible that the disease in West Africa, similar as it was in cause and effect, might act as a "feeder" to that in Europe and so tend to prolong its presence there. There was direct or indirect communication by means of caravans which might convey the infection between West Africa and many parts of North Africa from which the disease might be carried by ships to the seaports of Europe, where it was frequently found the epidemic started. Whether the infection was also air-borne had not been determined, but the direction of its spread in West Africa—roughly that of the prevailing wind—suggested that it might be to some extent, although its main mode of conveyance was by "contacts" as described. It was therefore, he submitted, of the utmost importance that every precaution possible should be adopted to arrest the disease in West Africa so far as could be done. Dr. Horn had described the steps taken for that purpose during the present epidemic and he suggested that in any future outbreak they should be rigorously enforced, together with any other means which might appear advisable, such, for instance, as nasal disinfection, a measure which was, however, entirely impracticable at present among natives.

A discussion followed, which was taken part in by Lieutenant-Colonel A. E. WATHERSTON, Dr. F. M. SANDWITH, Dr. G. C. LOW, and the PRESIDENT, after which Dr. HORN briefly replied.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

A MEETING of this society was held on Oct. 8th, Mr. G. B. MOWER WHITE, the President, being in the chair.

The Work of the Research Defence Society.

Mr. STEPHEN PAGET read a paper on the Work of the Research Defence Society, in the course of which he said: Many of us remember the first Royal Commission appointed in 1875 to inquire into experiments on animals. The contrast is very significant between the evidence given before that Commission and the evidence before the present Royal Commission. Truly, as we turn from the one set of Blue-books to the other, we seem almost to pass into a new world. In 1875 the evidence was mainly physiological, and even in physiology there were no such triumphs to be declared as the present Royal Commission has lately heard with its own ears. As for pathology, next to nothing was said about pathology, and there was nothing said about bacteriology—nothing, at any rate, except one or two vague and splendid prophecies. Especially, that magnificent passage in Sir John Simon's evidence touching the nature of anthrax:—

> We are going through a progressive work which has many stages, and are now getting more precise knowledge of the contagium. By these experiments on sheep it has been made quite clear that the contagium of sheep-pox is something of which the habits can be studied, as the habits of a fern or a moss can be studied, and we look forward to opportunities of thus studying the contagium outside the body which it infects. This is not a thing to be done in a day or perhaps in ten years, but must extend over a long period of time. Dr. Klein's present paper represents one very important stage of a vast special study. He gives the identification of the contagium as something which he has studied to the end in the infected body, and which can now in a future stage be studied outside the body.

But, of course, a Royal Commission cannot live on prophecies. The evidence before the 1875 Commission is in great part retrospective and historical. The witnesses proved, past all possibility of doubt, the value and the necessity of experiments on animals, and with that proof the Commissioners were content. They sat for six months only, they examined 53 witnesses and no more, and the total number of questions and answers attains the comparatively moderate figure of 6551. The Act founded on their recommendations was passed in 1876. If prophecy be out of place before a Royal Commission it is even more out of place in an Act of Parliament. Therefore ever since 1876 we have seen the Act strained and pulled this way and that, so that it may somehow be applied to the growing needs of science. For example, there is even now no special certificate for inoculations, yet inoculations, with a few experiments of the nature of inoculations, are at the present time 96·5 per cent. of all experiments on animals. Thus the public are left to believe that severe operations are performed on animals without anæsthesia, and we all know what use is made of this defect in the Act by the opponents of these experiments. In 1882, six years after the passing of the Act, some of the chief members of our profession founded the Association for the Advancement of Medicine by Research; among them were Lord Lister, Sir James Paget, Sir William Gull, Sir William Bowman, Sir Richard Quain, and Sir Andrew Clark. The purpose of this association was "to bring the legitimate influence of the medical profession more effectively to bear on the promotion of those exact researches in physiology, pathology, and therapeutics which are essential to the sound progress of the healing art." The council of this association made an offer to the Home Office "to render, within their province, such aid or advice as would tend to facilitate the administrations of the statute, without trenching upon the absolute discretion committed to the Home Secretary." This offer was immediately accepted by Sir William Harcourt, then Home Secretary, and in December, 1882, it was decided that no application under the Act should be entertained by the Home Office except on the recommendation of the council of this association. From that time till now, for more than a quarter of a century, this association has been the constant adviser of the Home Office. But we need not stay over these old facts about science and politics more than 30 years ago. The Act had hardly received the Royal Assent

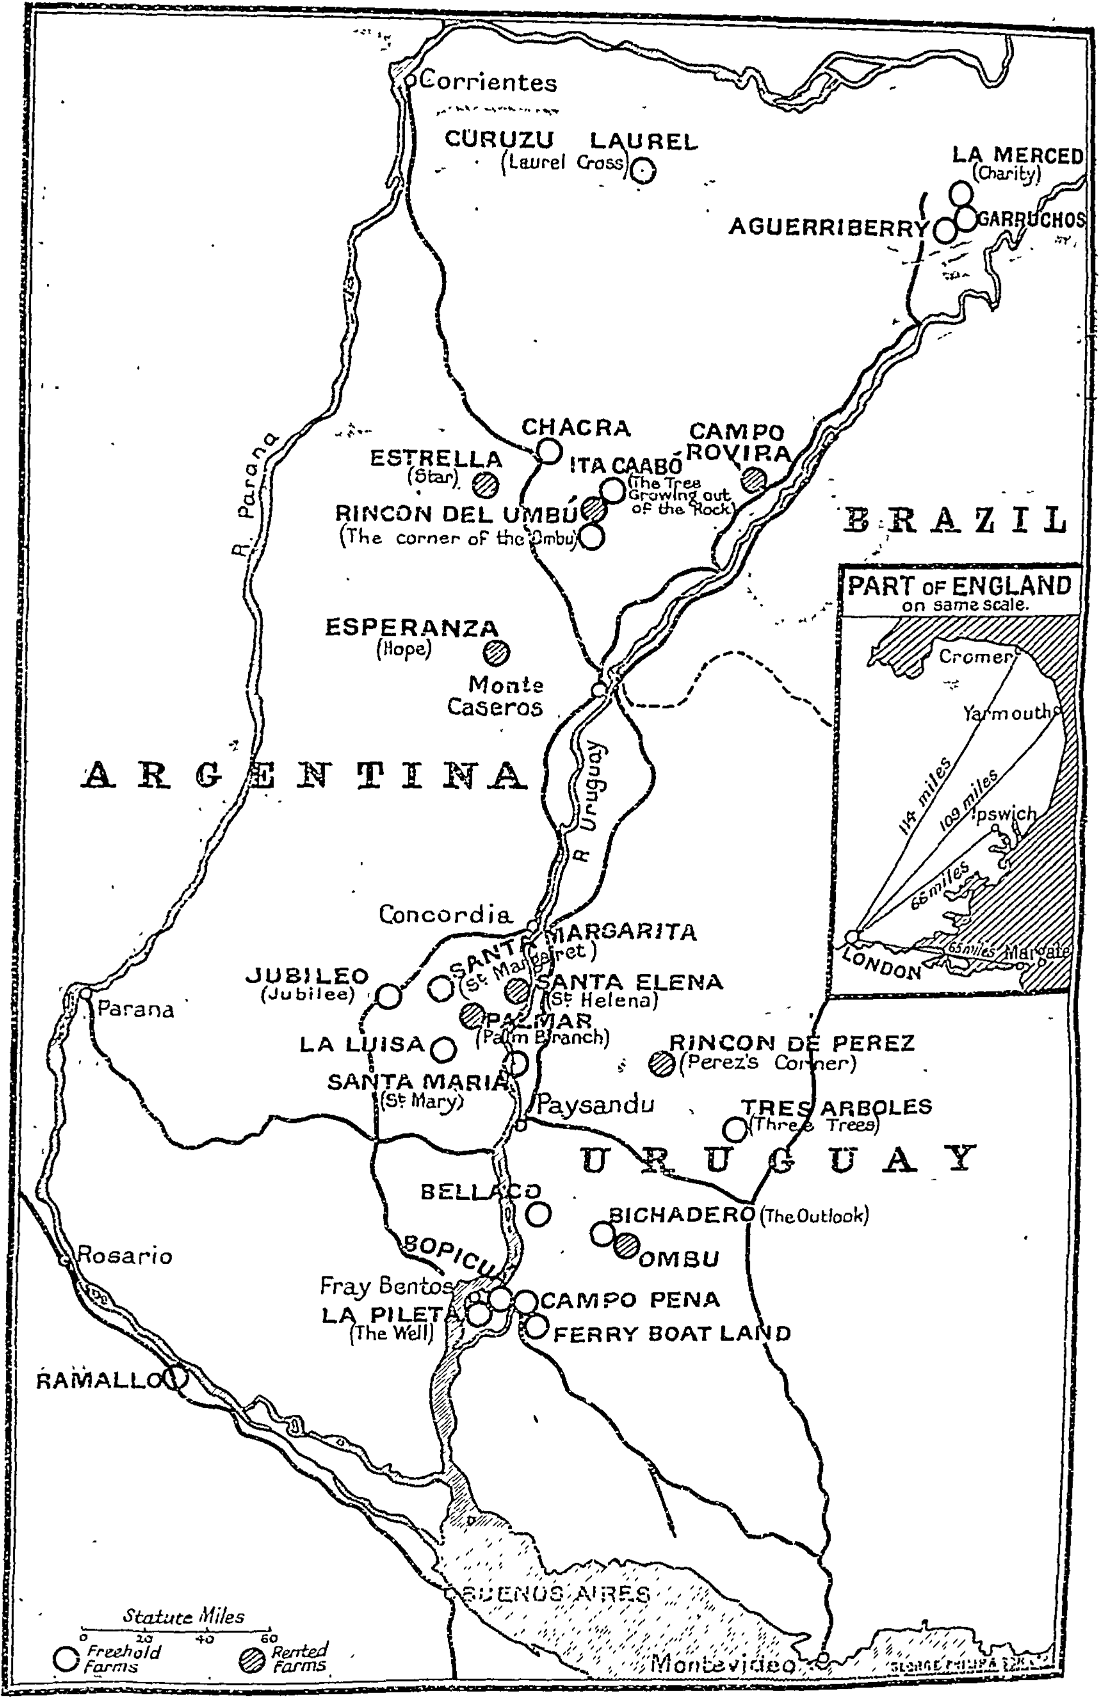

FIG. 3.—Map of the *estancias* on the Liebig Company's estates in Uruguay and Argentina.

Mr. S. Maynard Smith, and Mr. C. I. Graham.—Mr. T. Crisp English showed the following specimens: (1) A Fibro-adenoma of the Breast of great size, which was removed from a patient who was five and a half months pregnant; (2) a Malignant Growth of the Prostate Gland removed by him from a patient aged 70 years; and (3) a Twisted Calcified Fibroid of the Uterus of great size, which had caused symptoms of intestinal obstruction. The tumour was removed by operation.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The first meeting of the winter session of this society was held on Oct. 14th, when an address was given by Dr. L. S. McManus, the President, on General Practitioners in Relation to Each Other, to the British Medical Association, and to the General Medical Council. A brief sketch was given of the relationship of medical men to one another in the past, illustrating by examples culled from history, art, and literature, how our predecessors suffered like medical men of to-day from evils arising out of professional rivalries and jealousies and misconceptions on the part of the public; it was pointed out how the formation of societies such as the South-West London and on a larger scale of the British Medical Association had ushered in an era of greater kindly feeling and coöperation in which much good work had been done. Owing to the failure of the British Medical Association to fulfil the objects for which it had been founded, of late years it had been found necessary to revolutionise it and to place it on a broad democratic basis with many and varied functions designed for the advantage of every individual member as well as of the profession as a body. The General Medical Council was instituted for the protection of the public, and its main function, which had been adequately performed, was the supervision of the mental equipment of every student. The Council, however, lamentably failed to afford any protection to the practitioner when once qualified, a failure due to the insufficient representation of the general practitioners. In conclusion, the President urged on all practitioners the necessity of combination if the profession were to maintain its rightful position.

Reviews and Notices of Books.

Applied Physiology: A Handbook for Students of Medicine. By ROBERT HUTCHISON, M.D. Edin., F.R.C.P. Lond. London: Edward Arnold. 1908. Pp. 298. Price 7*s.* 6*d.* net.

THIS is an attempt, and a successful attempt, to apply physiology to medicine in the same way as anatomy has long been applied to surgery. It is intended to be a companion to, and not a substitute for, physiological text-books. An account of method is omitted: the chief emphasis is laid upon facts which have a direct bearing upon clinical work. There is no chapter on muscle, nerves, or the special senses. What is included is physiology as applied to metabolism (pp. 48), body heat (pp. 22), blood and hæmopoietic organs (pp. 34), heart and circulation (pp. 72), respiration (pp. 48), digestion (pp. 53), and excretion (pp. 20).

In connexion with the question of the metabolism of proteins, Chittenden's estimate of 60 grammes per day instead of 118 is mentioned and the author remarks, "it would be well for the physician to be cautious in applying these results in practice." Experience has shown the value of a liberal meat diet in tuberculosis, while the Japanese have found that a liberal meat diet given to their sailors is a prophylactic against beri-beri. A person cannot be made strong by a liberal protein diet, exercise must be taken at the same time. Massage has no appreciable influence on metabolism and is therefore in no real sense a substitute for exercise. Metabolism is treated from the quantitative point of view, expenditure and income of energy, storage of surplus energy, and then is set forth the influence of age, sex, build of the body, work and rest, season, period of day and weather, nervous system, internal secretions, and personal peculiarity on metabolism. Qualitative metabolism is then dealt with, including proteins, fats, and carbohydrates, which leads up to the consideration of diabetes and the metabolism of uric acid.

Sometimes the temperature is given in degrees Fahrenheit, sometimes in degrees Centigrade. The blood itself is considered not only as a medium of exchange and as a tissue, but also as a means of defence, and hence the importance of its antitoxic and bactericidal properties; and for this reason "hæmatology" has assumed a very important place in latter-day medicine. The term "apex beat" is retained for cardiac impulse. The nervous mechanism of the heart apparatus is carefully considered in relation to disease, while a general account of the chief facts of the circulation on which physiologists are agreed is supplemented by clinical facts. The capillary pressure is stated, on the authority of Hill, as being often above 100 millimetres of Hg. "Cold contracts the peripheral arteries and raises the blood pressure, so that the first onset of cold weather in winter is apt to be attended by a crop of apoplexies" (p. 165). The splanchnic nervous system is the "resistance box" of the circulation. Ludwig long ago pointed out the importance of the portal system in the regulation of the arterial blood pressure.

Special emphasis is laid on nose-breathing and the whole treatment of the respiratory processes is eminently scientific as well as practical. The treatment of certain conditions by inhalation of oxygen has justified itself in practice (p. 213), and the author quotes French writers on the effects of decompression in "caisson disease," when they say "payment is only made on coming out." Deep breathing is no substitute for exercise, this alone can really increase the oxidation processes in the body. The researches of Pawlow, of Cannon, and Hertz are woven into the story of the digestive processes and their practical applications are fully stated.

We feel sure that this work will prove useful not only to the student beginning his clinical work but also to the practitioner who has long since "walked the hospitals." It is written in a style at once simple and attractive which makes the assimilation of the facts both easy and effective. The salient facts of physiology find their appropriate application in the study of the phenomena of disease.

Atlas Chirurgisch-pathologischer Rontgenbilder. Mit 240 autotypischen, 105 photographischen Bildern, 66 Skizzen und erläuternden Text. (*Atlas of Radiograms of Surgical Diseases.* With 240 autotype and 105 photographic figures and 66 sketches and explanatory text.) By Dr. RUDOLF GRASHEY, Assistenzarzt der K. chirurgischen Klinik zu München. Lehmann's Medizinische Atlanten, Band vi. Munich: J. F. Lehmann. 1908. Pp. 152. Price M.22.

THE above work, as the title infers, is confined solely to the consideration of surgical diseases. It is divided into two parts. The first consists of 49 pages devoted to a short consideration of the following subjects: foreign bodies, concretions, diseases of bone, diseases of joints, deformities, tumours, pathological changes in the soft parts, dislocations, and fractures. The chapters on the location of foreign bodies and on the diseases of bone are by far the best; the others are a little disappointing, especially the scanty notice given to renal calculi.

The second part consists of numerous reproductions of typical radiograms with very full descriptions of each plate. Here there can be nothing but praise for the excellent reproductions of the prints. The difficult problem of bringing out the minute texture of the bones in book prints seems to have been solved most satisfactorily. In fact, the reproductions are as good as successful positives. In the

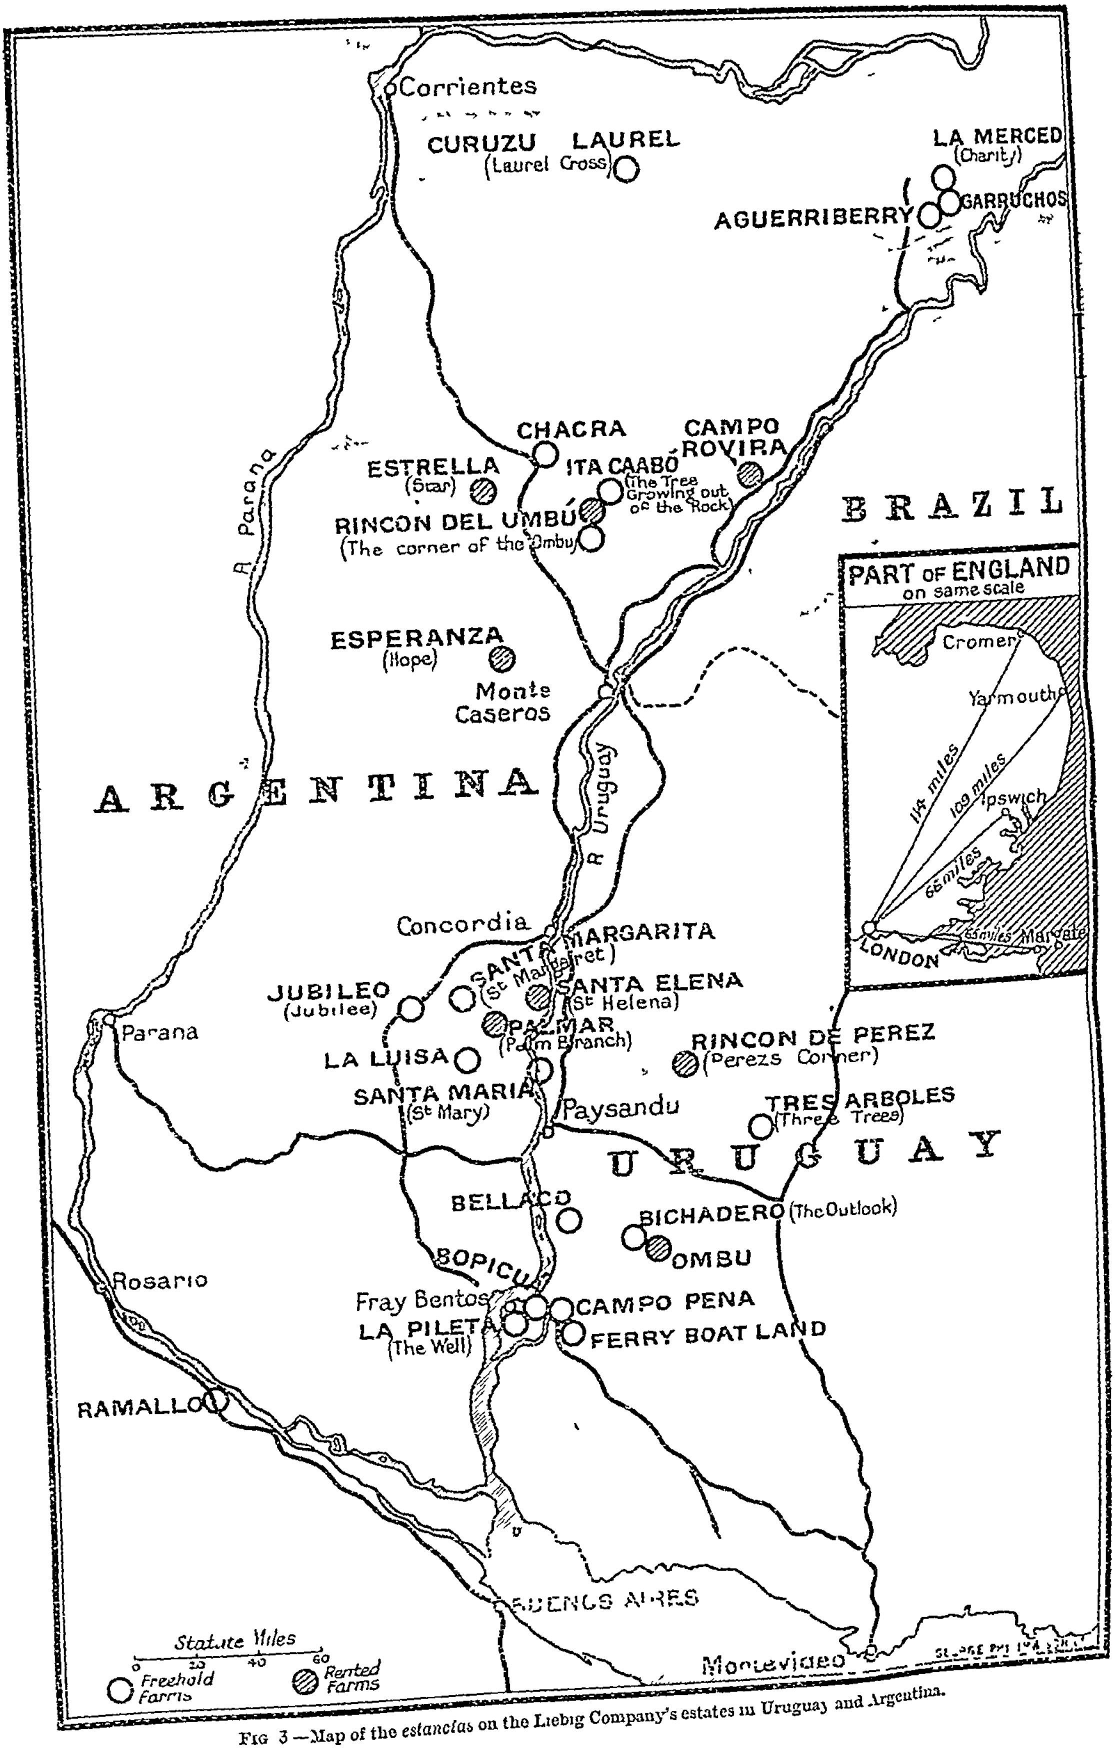

FIG 3.—Map of the *estancias* on the Liebig Company's estates in Uruguay and Argentina.

connective tissue that would take place between the testicle and the skin, through its power of contraction, would have a bad effect upon the functional capacity of the organ." We believe this idea to be entirely imaginary. The book is fully illustrated and we may specially mention an excellent plate showing a skiagram of a patient who had a double ureter on one side. All the three ureters have been catheterised through their length with catheters giving an x-ray shadow and the result is very striking.

Gonorrhœa: Its Diagnosis and Treatment. By FREDERICK BAUMANN, Ph.D., M.D., Professor of Genito-urinary Diseases in the Reliance Medical College, and Instructor in Dermatology and Venereal Diseases in the College of Physicians and Surgeons, Chicago. With 52 illustrations in the text. London: Sidney Appleton. 1908.—Gonorrhœa is now considered to be a much more serious disease than formerly, for it is recognised that diseases of many distant structures may be among its manifestations. This work, however, deals almost entirely with gonorrhœa as it affects the lower genito-urinary passages. A brief account is given of the anatomy of the urethra but no illustration is supplied. The description of the pathology of the disease is based on the work of Oberländer and Kollmann, and it is therefore very satisfactory. The treatment of the disease is naturally of the greatest importance and this is given at great length. The author has no very high opinion of internal treatment; he says that it may be used particularly in cases in which there is a marked purulent discharge, but he adds that it is that part of the treatment which may be omitted. He considers of much greater importance the local application of germicides and he discusses the relative value of the more commonly used urethral germicides. He has a low opinion of the organic preparations of silver but his objection to them appears to be, in part at least, theoretical. In the treatment of acute gonorrhœa he considers that the best results are obtained by daily irrigation with a warm potassium permanganate or nitric acid solution in increasing strength and given with a hand syringe without the use of an injector. The first injection should consist of one or two quarts of a 1 in 10,000 or 1 in 20,000 aqueous solution at a temperature of 40° to 45° C. The account of gonorrhœal metastases is very brief. On the whole, we consider that this book is likely to be useful as an introduction to the study of gonorrhœa.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—An interesting article upon osseous new growth at the elbow following backward dislocation of the bones of the forearm is contributed to the October number of this magazine by Mr. David M. Greig. The condition is of importance as accounting for some failures to produce a mobile joint after accidents of this nature which may bring discredit upon the surgeon. The author objects to the view that the ossification is to be regarded as a traumatic myositis ossificans and holds that the new bone is formed in effused blood clot. Dr. Claude B. Ker writes on the treatment of cerebro-spinal meningitis by Flexner's serum which he regards as a valuable remedy, and Dr. F. Parkes Weber raises a theoretical objection to the employment of Calmette's ophthalmic reaction in tuberculosis, in that it may set up recurring attacks of conjunctivitis due to subsequent auto-inoculations with tuberculous toxins.

The Medical Chronicle.—In the October issue of this journal Dr. Robert Ollerenshaw records some valuable investigations as to the nature and use of some of the newer hypnotic and analgesic drugs. Thus chloretone is valuable in sea-sickness and chorea, also as a preventive of post-anæsthetic vomiting, but useless as a local anæsthetic and of little value as a hypnotic; brometone is of value in some cases of epilepsy and has some hypnotic power; phenalgin is toxic and its advantages as an antipyretic are outweighed by its depressing action on the heart. Veronal is a valuable hypnotic and has the peculiar property of counteracting the unpleasant effects of morphine; bromural is also a useful and safe hypnotic; isopral acts similarly and can be administered by rubbing it into the skin. Neuronal has some power of inducing sleep but is unduly depressing. Mesotan is useful as a local application to rheumatic joints. Dr. J. Dixon Mann discusses the fallacies inherent in Fehling's test for sugar in the urine and shows that they are not serious in actual practice.

West London Medical Journal.—The October number of this journal opens with an interesting address by Colonel T. Holbein Hendley, I.M.S. Bengal (retired), upon the identity of the problems, aims, and interests of the medical man at home and abroad, with special reference to India. Dr. A. Elliott and Dr. A. E. Russell discuss some of the causes of unconsciousness and their diagnosis; and some interesting cases are recorded—two of purpura hæmorrhagica successfully treated by Dr. J. A. Coutts with antistreptococcic serum, and one of pancreatic hæmorrhage by Mr. Herbert W. Chambers.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Oct. 15th, Mr. HENRY MORRIS, the President, being in the chair.

Mr. EDMUND OWEN, on behalf of the Committee on the Annual Report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 19th. The report was approved.

Mr. Ernest Harries Walker, lately a student at Epsom College and now at St. Thomas's Hospital, was appointed the sixteenth Jenks scholar.

Sir W. Watson Cheyne was appointed a member of the committee of management in the vacancy occasioned by the retirement of Mr. Edmund Owen, to whom the thanks of the Council were given for his services on that committee.

Mr. P. Sidney Spokes was re-elected a member of the Board of Examiners in Dental Surgery.

Dr. Benjamin Moore, professor of bio-chemistry in the University of Liverpool, was elected examiner in physiology for the Second Examination of the Conjoint Examining Board in the vacancy occasioned by the death of Dr. Bertram Abrahams.

A letter was read from Mr. Henry T. Butlin, resigning his membership of the Senate of the University of London as one of the representatives of the College. A vote of thanks was given to Mr. Butlin for his services and Mr. H. H Clutton was appointed a representative of the College in his stead.

Mr. Clutton was also appointed an additional delegate on the joint committee with the Royal College of Physicians of London on the proposed combination with the University of London.

Mr. CLINTON T. DENT proposed the following motions which were carried:—

1. That steps be forthwith taken to admit women to the examinations of the Conjoint Examining Board in England and to the examination for the Diploma in Public Health.
2. That women be admitted to the examinations for the Fellowship of the Royal College of Surgeons and to the examinations for the Licence in Dental Surgery.

A committee was appointed to prepare a *formula* for the necessary alterations in the by-laws.

A BATH CENTENARIAN.—Miss Marianne Hensley of 4, Bloomfield-place, Bath, attained the 103rd anniversary of her birthday on Oct. 15th. The King sent a telegram of congratulation to Miss Hensley.

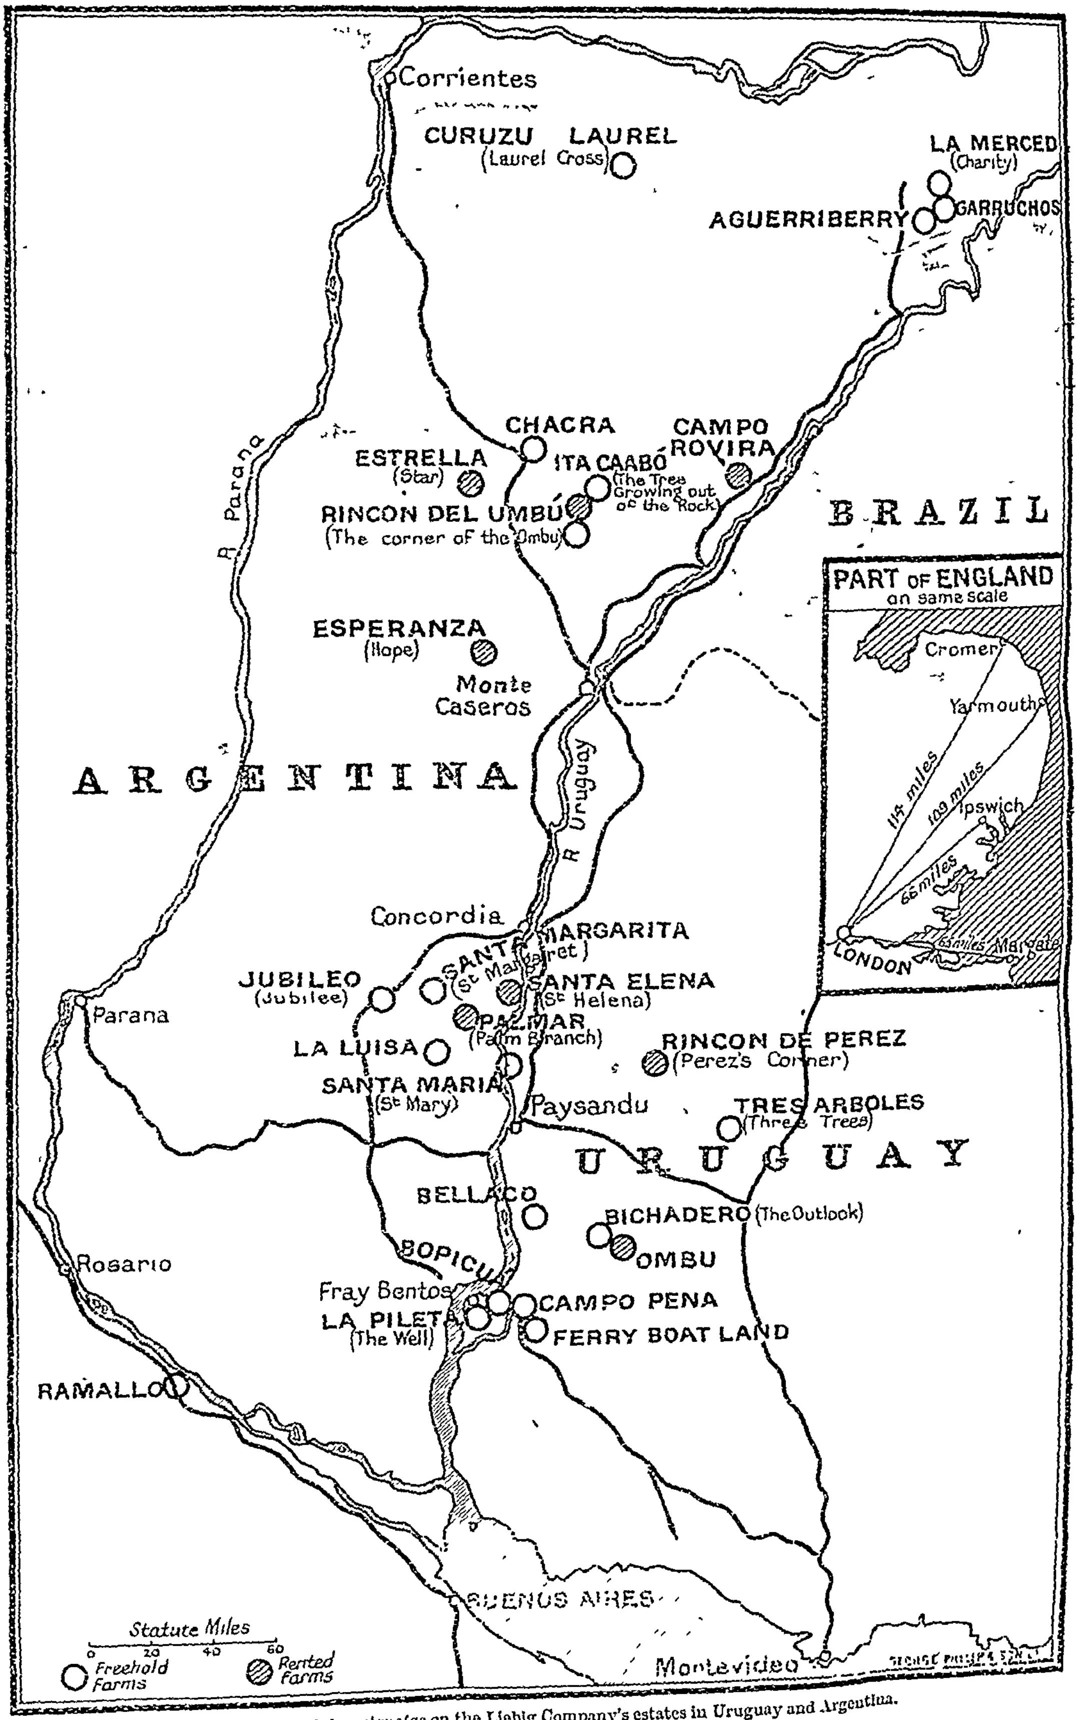

Fig. 3.—Map of the *estancias* on the Liebig Company's estates in Uruguay and Argentina.

defeat of the intentions of the legislature. Moreover, by a curious perversion of argument, the statement of the Poor-law medical officers that their appointments are in many cases held for the sake of the vaccination fees has been used by professional anti-vaccinationists to show that either these fees are excessive or that medical men who do not believe in vaccination are seduced by them into accepting the offices to which they are attached. The imputation of motives is a weapon which can scarcely fail to wound the hands which wield it. Mankind only impute to others motives analogous to those which they recognise as the springs of their own conduct.

Indications have not been wanting of late years that there are forces in operation at the Local Government Board which tend to look with less benevolence upon fees paid to medical men than upon those paid to the members of other callings. Notwithstanding this it is manifest that the Board has now fallen under the control of very strong hands and that the President is fully alive to the importance of the great sanitary work which is committed to his control. To this work the Poor-law medical service contributes in a degree which it would be difficult to exaggerate, and which will soon be materially increased by the Order by which the President is about to impose upon its members the duty of notifying to the local medical officer of health all cases of pulmonary tuberculosis which fall under their official cognizance. It is manifest that in this, as in all other departments of its work, the service is likely to be more effective in proportion as its position in the State is rightly recognised and rewarded. The conditions of different districts, of different forms of industry, and of different populations are so different that nothing like uniformity of those of the service itself can be expected; and such uniformity, if it were obtained, would soon be changed into diversity by the growth and the movements of populations. But the great difficulty of poor-law medical officers arises from the extent to which skill and knowledge have been placed under the control of ignorance and prejudice. Politicians have been eager for what they have described as popular local government, and they have not realised that good government requires a degree of knowledge which is never too abundant, which they have taken no pains to secure, and which in many districts is conspicuous only by its absence. There are scores of boards of guardians who have no other object than the accomplishment of any sort of little saving which the letter of the law may permit. Such bodies are wholly unfit to be intrusted with the control of an important branch of sanitary administration and their unfitness is nowhere more thoroughly known or more completely appreciated than at the Local Government Board. It is probable that no important changes can even be expected until the report of the Royal Commission on the Poor-law has been issued; but that report will almost certainly lead to legislation and will probably afford Mr. BURNS an opportunity, of which we believe he would not be slow to avail himself, of making changes in the system of medical relief by which the more serious grievances of the service would be removed. The public conscience is awakening to a recognition of the importance of the health of the poor as a factor in the general prosperity of the nation, and it is not likely that the officials to whom the care of that health is mainly committed will be left permanently under the control of bodies whose unfitness for the responsibilities imposed upon them is too often beyond the reach of doubt.

Francis Bacon of Verulam.

THESE are the days of tercentenaries and quatercentenaries, the homage paid by posterity to the master-builders of its platform and "coign of vantage." Of these "makers of empire" in the intellectual as well as material world none has stronger claims to present-day gratitude than the author of the "Novum Organum," that Magna Charta of inductive research to which experimental science owes a palingenesis, a new departure, justified, like Wisdom, of all her children. True, as a manual of method, it contains nothing that may not be elicited from the Organon of ARISTOTLE; its errors of omission and commission are patent to less competent critics than HUMBOLDT or LIEBIG; nay, it is demonstrable that not one single discovery or invention has been made upon its special lines. All the same, nothing can rob it of its distinctive merit—that of disenthralling the post-Renaissance mind from the fetters and manacles of tradition—tradition based upon an "Aristotelianism" which ARISTOTLE would have been the first to disown, tradition elaborated by the mediæval Church for ends no doubt laudable in their promoters' eyes, but fatal, in the sheer selfishness of their "objective" and in their very *modus operandi*, to the consummation which they professed to have in view. And yet BACON was, *toto cælo*, removed from the materialist, in whose hands—

> "Philosophy, that leaned on Heaven before,
> Sinks to her second cause, and is no more."

"I would rather," he says, "believe all the fables in the Talmud than that this mighty frame was without a Mind." From the beginning to the end of his philosophic writings there is audible but one note, that of reverence; there is present but one attitude, that of humility. In this spirit and with this demeanour he is content, nay, inspired, to think and to act as what he calls the "Naturæ minister et interpres," as one who wooes and wins Nature only by obeying her, and that implicitly and unreservedly. By such an address and by such a service, and by no other means, is the Truth, signifying the life of Nature, to be reached, and that not by the individual man or by any generation of mankind, but by Humanity itself coöperating through the ages. "Veritas temporis filia," he devoutly says, improving on the adage of the great Greek lyric poet:—

> ἀμέραι ἐπίλοιποι
> μάρτυρες σοφώτατοι.

Indeed, in the service of Truth one supreme virtue must be practised, that of patience. Having put her to the question, we must not, as he says of PILATE, refuse "to wait for an answer."

The Honourable Society of Gray's Inn, in its celebration of the third centenary of BACON's official connexion with its House, did well to invite the representatives of other professions besides that of the Law. Divinity and Medicine, as well as Affairs Imperial and Municipal, were equally in evidence at the ceremonial banquet—thereby attesting the universality of interests, the essential month and to see that only such carcasses as are free from all disease are allowed to be converted into food products. He further is bound to certify that every carcass showing any indication of disease whatever has been entirely disposed of for manurial purposes and in a way which prevents their consumption by human individuals. The regulations enforced in the slaughter-house in regard to the workpeople are modelled on similar sanitary demands. It is the duty of the foreman to report to the management any breach of the factory regulations on the part of any of the workpeople. He further must satisfy himself by inspection that the hands of the workpeople are absolutely clean and that no person suffering from any cutaneous disease is allowed to enter any department of the factory of which he is in charge. Finally, the medical inspector is authorised to inspect the workpeople employed at any time he may choose in order to convince himself that no breach of sanitary rule is committed. Our Commissioner made continual tours of the slaughter-houses, and at no time, he reports, was there any evidence other than that the sanitary regulations were being properly and rigidly enforced.

In the ultimate disposal of the various parts of the carcass of the freshly slaughtered animal there is nothing left to waste. At every stage utilisation is aimed at and every part is resolved into a material which is applied in one way or another to a useful purpose. This is one of the facts about this particular industry which invariably impresses the visitor. The metamorphosis of grass, to revert to an expression already used, is indeed a wonderful process, culminating as it does in the harvesting of such a variety of products. First may be mentioned the hides which with due skill and care bestowed on their preparation are an obviously valuable asset; then come the fatty portions, a proportionally big yield which may be directly consigned for food purposes (butter substitutes, for example), or for the manufacture of soap, glycerine, and so forth; next the bones for the preparation of bone meal, or the smaller ones which are used for preserving the shape of certain garments—e.g., corsets—then the sinews a source of glue of various grades, the scraped and cleaned intestine for sausage skins, the blood for producing a fine dry powder which supplies the elements essential in a fertilising material for agricultural purposes, and so forth. Incidentally there are residues necessarily accumulated in many of the processes carried out which nevertheless provide, when suitably treated, a material of value, and hence is returned to the soil in the form of a fertilising agent to complete the cycle of adaptation and usefulness. Separately treated are the various portions of meat which reach the public in the shape of corned beef, the processes involved being conducted with every regard to wholesome requirements, and then there are the tongues preserved in jelly which provide, in the view of a very large class of consumers, an excellent, sound, and appetising food. In connexion again with this class of food a periodical system of examination is kept in force and monthly reports are issued certifying that all the meat and tongues entering the factory are carefully examined and nothing is passed except such as is of good fresh quality. A similar inspection is made by the veterinary surgeon who periodically certifies that only sound good meat is allowed to be converted into food products and that in the event of carcasses or organs showing any disease they are at once consigned to the manure works where, it need hardly be said, the processes are drastic enough to destroy all germs of disease.

WATER-SUPPLY.

We have incidentally referred in the above account of the slaughter-houses and the processes conducted there to the great importance of a pure and plentiful water-supply being at hand. The meat-rearing industry would be completely paralysed without a generous supply of water at hand. Apart altogether from the question of rainfall which drops fatness on the land, furnishing thereby a plentiful pasturage, water is a first necessity in connexion with manufacture and particularly with a manufacture which deals exclusively with the preparation of animal foods from raw animal materials. A plentiful and trustworthy water-supply spells success but a shortage means disaster. The unfailing water resources of the Argentine and neighbouring States are the magnificent asset of these countries, which not only renders agricultural enterprise a commercial success but adds to this success by qualifying it by the application of hygienic standards. The supply of water is practically illimitable, but a question of equal importance, and which may be discussed next, is obviously that of its quality. Before giving the results of the analysis of samples taken by our Commissioner at both factories of the raw river water and the water after filtration, it may be pointed out that the company itself causes periodical analysis to be made, and every month a certificate is issued which insures that the quality is pure and good and fit for human consumption and for the preparation of the various food products. The filters are constructed on approved lines and are of large

defeat of the intentions of the legislature. Moreover, by a curious perversion of argument, the statement of the Poor-law medical officers that their appointments are in many cases held for the sake of the vaccination fees has been used by professional anti-vaccinationists to show that either these fees are excessive or that medical men who do not believe in vaccination are seduced by them into accepting the offices to which they are attached. The imputation of motives is a weapon which can scarcely fail to wound the hands which wield it. Mankind only impute to others motives analogous to those which they recognise as the springs of their own conduct.

Indications have not been wanting of late years that there are forces in operation at the Local Government Board which tend to look with less benevolence upon fees paid to medical men than upon those paid to the members of other callings. Notwithstanding this it is manifest that the Board has now fallen under the control of very strong hands and that the President is fully alive to the importance of the great sanitary work which is committed to his control. To this work the Poor-law medical service contributes in a degree which it would be difficult to exaggerate, and which will soon be materially increased by the Order by which the President is about to impose upon its members the duty of notifying to the local medical officer of health all cases of pulmonary tuberculosis which fall under their official cognizance. It is manifest that in this, as in all other departments of its work, the service is likely to be more effective in proportion as its position in the State is rightly recognised and rewarded. The conditions of different districts, of different forms of industry, and of different populations are so different that nothing like uniformity of those of the service itself can be expected; and such uniformity, if it were obtained, would soon be changed into diversity by the growth and the movements of populations. But the great difficulty of poor-law medical officers arises from the extent to which skill and knowledge have been placed under the control of ignorance and prejudice. Politicians have been eager for what they have described as popular local government, and they have not realised that good government requires a degree of knowledge which is never too abundant, which they have taken no pains to secure, and which in many districts is conspicuous only by its absence. There are scores of boards of guardians who have no other object than the accomplishment of any sort of little saving which the letter of the law may permit. Such bodies are wholly unfit to be intrusted with the control of an important branch of sanitary administration and their unfitness is nowhere more thoroughly known or more completely appreciated than at the Local Government Board. It is probable that no important changes can even be expected until the report of the Royal Commission on the Poor-law has been issued; but that report will almost certainly lead to legislation and will probably afford Mr. BURNS an opportunity, of which we believe he would not be slow to avail himself, of making changes in the system of medical relief by which the more serious grievances of the service would be removed. The public conscience is awakening to a recognition of the importance of the health of the poor as a factor in the general prosperity of the nation, and it is not likely that the officials to whom the care of that health is mainly committed will be left permanently under the control of bodies whose unfitness for the responsibilities imposed upon them is too often beyond the reach of doubt.

Francis Bacon of Verulam.

THESE are the days of tercentenaries and quatercentenaries, the homage paid by posterity to the master-builders of its platform and "coign of vantage." Of these "makers of empire" in the intellectual as well as material world none has stronger claims to present-day gratitude than the author of the "Novum Organum," that Magna Charta of inductive research to which experimental science owes a palingenesis, a new departure, justified, like Wisdom, of all her children. True, as a manual of method, it contains nothing that may not be elicited from the Organon of ARISTOTLE; its errors of omission and commission are patent to less competent critics than HUMBOLDT or LIEBIG; nay, it is demonstrable that not one single discovery or invention has been made upon its special lines. All the same, nothing can rob it of its distinctive merit—that of disenthralling the post-Renaissance mind from the fetters and manacles of tradition—tradition based upon an "Aristotelianism" which ARISTOTLE would have been the first to disown, tradition elaborated by the mediæval Church for ends no doubt laudable in their promoters' eyes, but fatal in the sheer selfishness of their "objective" and in their very *modus operandi*, to the consummation which they professed to have in view. And yet BACON was, *toto caelo*, removed from the materialist, in whose hands—

> "Philosophy, that leaned on Heaven before,
> Sinks to her second cause, and is no more."

"I would rather," he says, "believe all the fables in the Talmud than that this mighty frame was without a Mind." From the beginning to the end of his philosophic writings there is audible but one note, that of reverence; there is present but one attitude, that of humility. In this spirit and with this demeanour he is content, nay, inspired, to think and to act as what he calls the "Naturæ minister et interpres," as one who wooes and wins Nature only by obeying her, and that implicitly and unreservedly. By such an address and by such a service, and by no other means, is the Truth, signifying the life of Nature, to be reached, and that not by the individual man or by any generation of mankind, but by Humanity itself coöperating through the ages. "Veritas temporis filia," he devoutly says, improving on the adage of the great Greek lyric poet:—

> *ἁμέραι ἐπίλοιποι*
> *μάρτυρες σοφώτατοι.*

Indeed, in the service of Truth one supreme virtue must be practised, that of patience. Having put her to the question, we must not, as he says of PILATE, refuse "to wait for an answer."

The Honourable Society of Gray's Inn, in its celebration of the third centenary of BACON'S official connexion with its House, did well to invite the representatives of other professions besides that of the Law. Divinity and Medicine, as well as Affairs Imperial and Municipal, were equally in evidence at the ceremonial banquet—thereby attesting the universality of interests, the essential

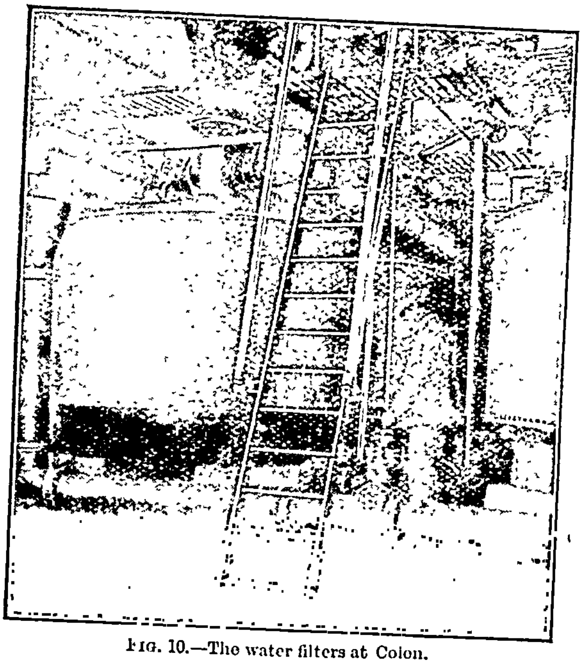

FIG. 10.—The water filters at Colon.

capacity, having regard to the enormous quantities of water required for cleansing and manufacturing purposes. A picture of one of the filters at Colon is given in Fig. 10. The filtering material is crushed pebble and sand. Subjoined are the analyses of No. 1 water from Colon (*a*) unfiltered, (*b*) (filtered); and No. 2 water from Fray Bentos, (*a*) unfiltered, (*b*) filtered.

As already stated, both factories derive their supplies from the Uruguay river which pours a colossal volume of water into the River Plate, Fray Bentos being about 100 miles from the estuary and Colon about 80 miles higher up. The unfiltered water in each case represents raw river water taken from a spot in the river near the intakes. It will be seen that the samples, though taken at spots many miles apart, show very little variation in regard to their composition or quality. The water is remarkably soft, the total dissolved mineral matter amounting to approximately five grains per gallon. As to evidences of organic impurity there are none, the total nitrogen contained in free ammonia, the albuminoid ammonia, and the nitrates respectively being a quite negligible quantity. Again, the oxygen consumed is very microscopic and the figure recorded is probably due entirely to a minute amount of plant débris. In short, the water is of excellent quality for all purposes, not excluding the refined requirements of human consumption. For manufacturing purposes it is splendidly adapted and must smooth the way very considerably for all the engineering methods employed in the factory. The water is slightly opalescent which is due to very finely divided particles of clay. We have pointed out that the quantity of water for general purposes is illimitable and to this may now be added the fact that its quality leaves nothing to be desired, even having regard to the delicate purposes for which, as we shall next point out, it is required.

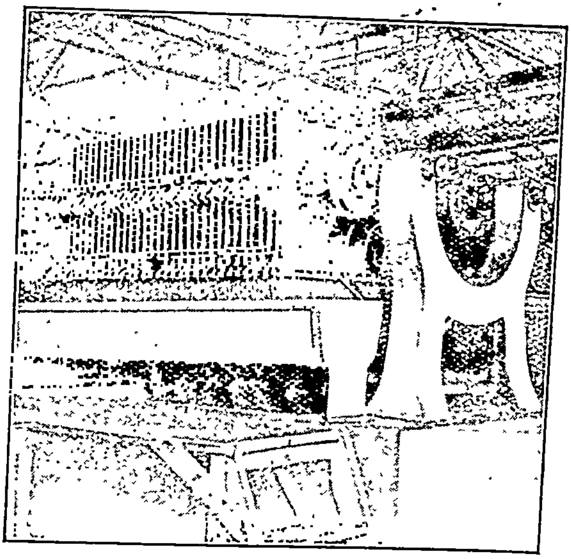

FIG. 11.—An extract filter.

LIEBIG'S EXTRACT OF MEAT (LEMCO).

Interesting and important as is the utilisation of the various animal products and foods enumerated in a preceding paragraph and the processes by which they are rendered valuable, we come next to consider the methods by which the extract of meat, as originally directed by Liebig, is made. In view of the immense popularity of this preparation and of the still increasing demand for it there can be little doubt that extract of meat fills an important gap in the common dietetic wants of the present day. In approaching, therefore, the questions which a consideration of the methods of its preparation and of its composition and physiological action raises we are dealing with perhaps the most important branch of the subject of the present inquiry. First, then, in regard to the preparation of the extract. In principle the lines first laid down by Liebig which he considered essential to success are still followed by the Liebig Company, who to secure to the consumer an article produced in accordance with his directions have distinguished it by the name of "Lemco," but it is obvious that an experience of nearly 50 years would lead to sundry improvements in the manufacture being introduced, and certain details have, as a matter of fact, been modified with the view, and with the actual result, it may be added, of producing what may be regarded as finality in regard to the quality of the product. Nevertheless, the process is perfectly simple. In the first place, the finest portions of meat are selected and these are reduced to the condition of mince-meat by machines especially constructed for the purpose. The meat mass is then transferred to large pans or kettles, each capable of holding four tons, in which it is left with its own weight of pure filtered water. After the addition of more water the mixture is carried to a temperature by means of steam jackets, the exact degree being determined by a consideration of the condition of the meat. Generally the temperature is between 80° and 94° C., but it is never allowed to exceed the last figure as otherwise the extract would contain gelatin. During this time fat continuously rises and is skimmed off. The more or less clear liquor is then run off and the work of concentration is commenced. Fat is again skimmed off until at length the watery extract or soup is practically free. The fat so skimmed off is of the very finest description, being that which occurs in the interstices of the meat cells. Concentration proceeds again in a vacuum vessel and at a certain point the liquor is filtered, concentrated again, and filtered again through a battery of filters known as a filter press, an illustration of which in given in Fig. 11. The final stage is reached when the now

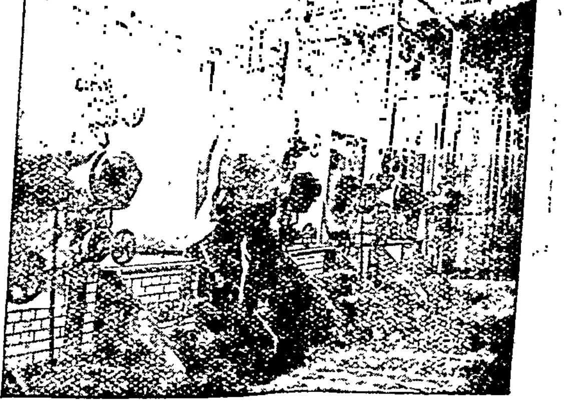

FIG. 12.—Series of mixers, each capable of dealing with 1 ton of extract mixture.

drained cowsheds in aiding the pollution of milk. The dust raised during sweeping or bedding the cows is loaded with organisms which may include the bacillus tuberculosis and the bacillus coli, or the bacillus of slimy milk. The practice of milking cows in the stalls where they are fed and housed is undesirable: the coming and going of cowkeepers, the traffic, and the movement of animals stir up a considerable amount of polluting material which finds ready access to the open milk pail. The use of milk-cans with large open tops and badly fitting covers and the system of keeping the dipping utensils suspended inside the milk-cans are practices which promote further contamination. Cans which are battered or the internal tin plating of which is worn off in patches are difficult to cleanse effectually; they enable a thin layer of bacteria to survive from one emptying to the next filling, ready to develop and to multiply in the fresh supply of milk. Cans insufficiently steamed or "cleansed" in polluted water, the use of dirty or infected cloths for cleansing purposes,—all these are fruitful sources of contamination. Milk utensils must not merely be "cleansed," they must be made bacteriologically or surgically clean. It no longer holds that "anything is good enough to clean a milk-can with"; the work requires care and consideration, which can only be appreciated by those who have received adequate instruction and training.

In the year 1906 the public analyst of Chester was requested, in forwarding analyses of samples of milk, to report on the nature of the sediment present, its amount, and its constituents. Later, the analyst reported that some of the samples contained a sediment consisting partly of cowdung, whereupon a general warning was issued against uncleanliness in milking, as well as in stabling and grooming cows, with an intimation that neglect of such precautions would lead to prosecution in future. Since that time several prosecutions have been instituted in respect of cowdung in milk and in five of them fines were inflicted. The effect of these legal proceedings upon the cleanliness of the milk has been marked, for whereas in former times it was not uncommon to find a slight brownish sediment at the bottom of the milk-jug, visible to the naked eye, such a sediment, although still present in the milk of large towns, is becoming rare in Chester. It will be generally conceded that any sample of milk obviously contaminated with cowdung should be unhesitatingly seized and destroyed, and, indeed, that contamination of milk with filth of any kind should be visited with severe penalty, if not with actual imprisonment of the offender.

The following are some of the chief suggestions offered by Dr. THOMAS for the improvement of the conditions commonly prevalent in farmhouses and dairies. The milker should be furnished with soap, towel, and nail-brush for use before each milking; he must be compelled to keep himself clean, for he has commonly as much aversion to cleanliness as has the tramp in the casual ward; a clean white overall should be worn during milking; and the cows should be kept well groomed and brushed—in fact, should be kept as clean as the horse. At present there is probably no animal in a farm, not even the pig, which is allowed to remain in such a filthy condition as is the cow. The hairs about the flanks, around the udders, the hindquarters, and the tip of the tail should be kept short. Clean bedding should be provided daily and the cow-byre should be cleansed at least an hour before the time of milking. The herd of cows should be periodically examined by a veterinary surgeon and any animal with diseased udder should be stopped at once from contributing to the milk-supply. As regards the storage of milk in milk-shops it is recommended that the milk should be kept in clean glazed porcelain vessels covered with muslin; it should be kept in a cool place at a temperature if possible below 40° F. The question of purity in our milk-supply is a vital one. The desire for pure milk is not a fad, a mere passing whim, though it is doubtful whether a large number of people even know the taste of "clean milk." Meantime, the demand is urgent for clean milk—milk that is free from pus and manure; milk that is fit for suckling children, nutritious, and free from disease germs—in short, milk that is milk, and nothing but milk. Unless this is to be obtained clean, wholesome, and satisfying, the time may, in Dr. THOMAS's opinion, come when its municipalisation or nationalisation may have to be considered seriously.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND AND WOMEN CANDIDATES.

IN 1876 a law was passed by which examining bodies granting diplomas or degrees qualifying for the practice of medicine were enabled to admit women candidates to their examinations. Many of the Universities and other medical examining bodies opened their doors to women candidates by virtue of this Act, but the Universities of Oxford and Cambridge and the Royal College of Physicians of London and the Royal College of Surgeons of England declined to follow the example of the rest. In 1895 a petition from the officers and teachers of the London School of Medicine for Women and the staff of the Royal Free Hospital and others interested in the matter was presented to the two Royal Colleges; it requested that the examinations of the Colleges should be thrown open to women candidates. At the Royal College of Physicians of London it was considered at an extraordinary Comitia of the Fellows and it was rejected by nine votes, 59 voting against the granting of the petition and 50 in favour of it. At the Royal College of Surgeons of England it met with a slightly different reception. It was considered by the Council advisable to refer it to the annual meeting of Fellows and Members and there it was resolved to reject the petition by 58 votes to 39. The Council of the College subsequently considered the petition and passed this resolution:—

> The Council of the Royal College of Surgeons of England, although in favour of granting the petition of the officers and teachers of the London School of Medicine for Women, do not see their way to admit women to the Conjoint Examination in face of the adverse vote of the meeting of the Fellows and Members of this College and the expressed opinion of the Royal College of Physicians.

There the matter rested for 12 years, till in the early part of last year a petition signed by a large number of medical men was presented to the two Royal Colleges asking for the admission of women candidates. In May, 1907, the Council of the Royal College of Surgeons passed the resolution that "in the opinion of the Council it is desirable that women be admitted to examination for the Diploma of Member," and it was resolved to approach the Royal College of Physicians on the matter. An extraordinary Comitia of the Fellows of the Royal College of that the extract reaches the public identical in composition and quality with that of the sample obtained directly from the distributing factory. The ranges in composition are as follows :—

Moisture	From	17·12	per cent. to	21·50	per cent.
Mineral salts	„	18·35	„	26·30	„
Organic matter	„	55·34	„	62·43	„
Total nitrogen	„	9·48	„	11·62	„
Albumose	„	8·52	„	14·26	„
Peptone	„	3·34	„	5·60	„
Total proteins	„	14·12	„	19·34	„
Creatine and creatinine...	„	9·00	„	12·50	„
Insoluble matter	„	0·25	„	0·88	„
Sodium chloride	„	2·68	„	5·69	„
Phosphoric acid (P_2O_5) ...	„	3·06	„	6·70	„

As a rule the samples taken directly from the producing factories are, it will be noted, slightly more concentrated than the market samples. Extract of meat will readily absorb moisture during transit in a damp atmosphere. In addition, the raw material itself, that is to say the meat, is seldom absolutely constant in regard to the amounts of its individual constituents. Perhaps the most constant figures in regard to the analysis of meat extract are the nitrogen, 10 per cent., and the creatine and creatinine, which amount to 10 per cent. also. It may be pointed out that the moisture in the above table represents in reality the loss sustained on drying at 120° C. This loss probably includes a small percentage of volatile organic matters.

Before proceeding to discuss the value of extract of meat from a nutritive point of view we may refer to a modified product called "Oxo," which is extract of meat or "Lemco" plus an addition of fine dry beef powder. The preparation of this powder is conducted with special care, particularly as regards reducing the meat to a very finely divided state. The best lean parts from the loins are cut up, minced, and slowly dried on steam-jacketed drying tables, after which the dry beef is ground and passed through exceedingly fine sieves and mixed ultimately with a definite proportion of extract. Our analysis of the powder was as follows :—

BEEF POWDER USED IN "OXO."

	Per cent.
Moisture...	9·20
Mineral salts	4·00
Organic matter	86·80
Total	100·00
Nitrogen	14·00
Fat	8·00
Sodium chloride	0·02
Phosphoric acid (P_2O_5)	2·90

In regard to this analysis, it is important to note that the powder represents about four times its weight of raw meat, because raw meat contains generally more than three-fourths of its weight of water. A definite quantity of this powder when incorporated with the extract of meat forms what is known as "Oxo," Fig. 12 illustrating a series of mixers for the purpose, each capable of dealing with one ton. As to the quantity so added, this appears from the analyses made in THE LANCET Laboratory (Table IV.) of a number of samples of "Oxo" which were purchased in the open market, as with the "Lemco" samples. The insoluble matters there shown practically represent, except for a small quantity of insoluble flavouring agents present, the amount of dry beef powder added. It lies between 4·91 and 7·24 per cent. This represents the addition of 19·64 and 28·96 per cent. respectively of fresh raw meat.

TABLE IV.—*Analyses of "Oxo" Purchased on the Open Market.*

—	*1*	*2*	*3*	*4*	*5*	*6*		*8*	*9*	*10*

Total protein	13·50
Creatine and creatinine	4·70
Insoluble matters	4·61
Fat	Traces.
Sodium chloride	8·46
Phosphoric acid (P_2O_5)...	4·88

There is further a preparation known as "Nursing Oxo," which is particularly intended for use in the sick room and contains, as our analysis given below shows, a comparatively high proportion of proteins derived from the peptonisation of meat. For the preparation of this adjunct pure beef is cut up and put into jacketed cylinders with about 30 per cent. of water. The cylinders are then closed and steam is admitted into the outer jackets. The liquid after being treated in this way for some time is then run off, filtered, and concentrated. It is rich in albumose, as the following analysis shows :—

ANALYSIS OF PEPTONE.

	Per cent.
Moisture	29·82
Mineral salts	8·33
Organic matter	61·85
Total	100·00

shown a very similar decline. The figures quoted above make it more than doubtful, however, whether there has been any decline in the number of occurring cases at all commensurate with the decrease of fatal cases, although the individual cases are without doubt very generally and steadily becoming slighter and milder in type. It would be interesting to know whether there is any connexion between this change in the type of the disease and the systematic notification and isolation of the cases, which have been increasingly adopted in recent years. Dr. Niven holds the opinion that the type of the disease would again become more severe if the proportional treatment in hospital were to be reduced. The case-mortality of scarlet fever treated in the hospitals of the Metropolitan Asylums Board did not exceed 2·94 per cent. in 1906 and 2·80 in 1907; and in Manchester the mortality of cases treated in hospital was 3·6 per cent. in each of those years. These percentages showed, both in London and in Manchester, a marked decline from the rates of case-mortality of this disease in former years. Dr. Niven gives in his report some elaborate and valuable statistics respecting "return" cases of scarlet fever arising from discharged hospital patients and concludes that the number of such cases, speaking generally, is insufficient to prevent hospital isolation being credited with a wide beneficial influence. Whatever may be the true explanation of the persistent prevalence of mild cases of scarlet fever it seems impossible to suppose that decrease of hospital isolation of cases of this disease could tend to reduce its general prevalence.

THERAPEUTICS BY RAIL.

CROSS-COUNTER consultations, followed by prescriptions, "sharp, short, and decisive," may be favoured by the "man in the street," but for the invalid at the continental health resort or the Mediterranean sun-trap there is the "table d'hôte clinique" and the "winter garden practice," no less irregular and deplorable. Satire, indeed, on the stage and in the novel, has revelled in the exposure of the valetudinarian dupe who confides his symptoms to some amateur adviser at the hotel or *pension* and who reaps the reward of his credulity by having at last to call in the practitioner whose visits would have been fewer and the sum total of whose fees would have been lighter had he seen the case *ab initio*. But, in the words of the philosopher Hume, "the fools of this world are a large and influential majority," and so long as the 'populus vult decipi" there will always be the cynic to add "decipiatur." A new accession to the resources of irregular practice has made itself prominent of late years, and that is the appeal addressed to the railway passenger by the advertisements that stud his line of route, inviting him to try this "pill" or that "tonic" or the other "mineral water" if he would rid himself of the many maladies which he is presumed to harbour. Within a few score yards of each other—recurring far more frequently than milestones—the wooden hoarding or the painted placard assures him that a remedy has at last been found for his "nervous trouble" or his "bilious headache" or his "chronic dyspepsia," and that he has only to invest in the special pill-box or bottled liquid to regain the health which he has vainly sought from the "faculty." So largely have the British railway lines been utilised for these manifestoes that the "foreigner," more or less "intelligent," after a short experience of travel in these islands, has described them to his compatriots as another of the many proofs of "Anglo-Saxon gullibility." Following up his observations, he is humorously concerned at what the British public can—in every sense—be made to "swallow," and, basing his remarks on a recent article in THE LANCET on the sale of "patent medicines" he astounds his audience with the calculation that last year the "medicinali brevettati" consumed in Great Britain amounted to 65,500,000. The *Gazzetta del Popolo* of Turin—a journal widely diffused throughout Italy—comments facetiously on the childlike faith of the "buoni Inglesi" who have made the fortunes of so many millionaires by their consumption of medicines professing to cure "qualsiasi morbo, dal coléra ad un semplice raffreddore" (any ailment whatever, from cholera to a simple cold in the head); and between the lines it holds out an inducement to the would-be millionaires of Italy to profit by similar methods at the expense of Italians. All this makes rather melancholy reading—fraught as it is with proof of the immense leeway that has yet to be made up at home and abroad by education, confirming, as it does, moreover, the pathetic, if not despairing, cry of Shelley—

> "How 'green' is this grey world!"

THE INVALID CHILDREN'S AID ASSOCIATION.

WE have received an appeal from the officers of this association stating that unless further funds are forthcoming it will be obliged to suspend its operations. This would be a great pity as the association is doing work of a very useful class in relieving children suffering from chronic diseases such as tuberculosis, rickets, chorea, and prolonged debility who cannot be kept in hospital sufficiently long to effect their cure and whose home circumstances render it impossible. The association has no buildings of its own but supports its beneficiaries in suitable nursing or convalescent homes in the country or by the sea until the medical man in charge pronounces the patient to be well enough to return home. Some cases have been treated thus for two years. It is in guaranteeing the cost of the weekly payments for these children that the association needs help, and it is thought that medical men might make its methods known to their well-to-do patients who are interested in children's charities. Another useful service that may be undertaken is that of visiting and keeping in touch with the association's children after their return to their homes and supervising the use of any surgical appliances or invalid carriages that may be supplied to them. This branch of the work was the original purpose of the association. We are asked to state that the secretary's office is at 69, Denison House, Vauxhall Bridge-road, London, S.W.

GANGRENE OF THE SKIN OF THE FOOT AFTER STOVAINE-ADRENALIN SPINAL ANÆSTHESIA.

FROM time to time untoward effects are recorded after spinal anæsthesia. The chapter of the dangers of this method has yet to be written. In the *Intercolonial Medical Journal of Australasia* for July Dr. D. Murray Morton has reported an unusual sequel—gangrene of the skin of the foot—which he describes as "unique amongst a very considerable number of administrations of stovaine-adrenalin during the last three years at St. Vincent's Hospital" (Melbourne). A debilitated man, aged 65 years, was admitted on Feb. 27th last suffering from two chronic ulcers in the lower part of the left leg. One began after a slight injury two years previously and the other spontaneously. There were no varicose veins and there was a doubtful history of syphilis. The urine did not contain albumin or sugar and the knee-jerks were present. On March 13th, under stovaine-adrenalin spinal anæsthesia, the ulcers were excised and Thiersch skin grafts were applied. Two-thirds of a cubic centimetre of a 10 per cent. solution of stovaine with half a cubic centimetre of adrenalin solution were injected into the spinal canal. There was no difficulty in the injection but a few minutes afterwards the patient showed symptoms of collapse. He vomited, the pulse became small, the face became pallid, and the respirations became very by restoring a tired muscle to activity. The chemistry of meat extract has by no means even now been exhausted, and there are still many constituents present in it which have not been definitely recognised and yet to which it may owe in part its valuable dietetic properties. Hence the arguments which have been put forward against the dietetic use of extract of meat have often received a crushing reply from the favourable results gained in actual practice. The fact, at all events, cannot be ignored that beef extract supplies a distinct human need, as is evidenced by its continued popularity for dietetic purposes for both the sick and the healthy and by the increased demand which has taken place for it during recent years. In view of this demand it is all the more satisfactory that, coming back to the chief purpose and aim of the present inquiry, our Commissioner as the result of his visit is able to report that the concentrated meat products of the Liebig Extract of Meat Company are prepared in strict pursuance of a policy which requires that every process from beginning to end shall be placed under scientific control and be made to comply with a hygienic *régime* which leaves no room for adverse criticism. The confidence of the management in the adequacy of the scientific and sanitary measures adopted at both factory and farm is such that invitations are cordially extended to medical men who may be visiting the Argentine to include in their travels an inspection of the arena of this great and important industry.

MEDICINE AND THE LAW.

The Use of Cocaine in the Extraction of Teeth.

A CASE of considerable importance to the dental profession was tried before Judge Ingham at Evesham county court on Oct. 17th. Thomas Abbott Stanley, auctioneer's clerk of Pershore-road, Hampton, Evesham, claimed from Walter Joseph Craven, druggist, Bengeworth, Evesham, £20 damages for injury to the plaintiff through the negligence of the defendant, his servant or assistant, in the extraction of a tooth and in the application to the gums of the plaintiff of cocaine. Mr. Hosgood appeared for the plaintiff and Mr. G. New for the defendant. It appeared that the plaintiff had a tooth extracted by the defendant's assistant who administered cocaine. Shortly afterwards the plaintiff was taken very ill indeed and was confined to his bed for over a week. He wrote to the defendant, who advertised "teeth painlessly extracted," that his cocaine had made him very ill and but for the attention paid to him by his mother and sister he (the defendant) would have had to answer a very serious charge before the court, and that Dr. D. Gordon-Evans, who had attended him, had said that if he had had a tenth of a grain more cocaine it would have killed him. The plaintiff said that the defendant's assistant Munslow poured the cocaine into a medicine glass and injected it into the gums with a syringe. He then commenced to extract the tooth but in doing so broke it in two. The witness suffered terrible pain. The assistant injected more cocaine and ultimately got the tooth out. Shortly afterwards the witness was taken ill and had to go to his mother's house where he was sick and shivered a lot. He was put to bed and a medical man was fetched, and in the meantime the witness became unconscious. He had since not been able to do his work so well as formerly and he had lost over a stone in weight. He had consulted a Worcester specialist and his nerves were still very much upset. He was charged 2*s.* for the "painless extraction." Dr. Gordon-Evans said that he found the plaintiff in a more or less insensible condition and in an extremely dangerous state and if it had gone on an hour or so more the plaintiff would have died. He was as near death as could be. The witness produced cocaine in tubes, saying that was the proper way to administer the drug and these contained the proper dose. It was not safe even for a fully qualified man to administer cocaine from an open glass, and Munslow was not qualified. It was a most dangerous and deadly drug. He thought that the plaintiff's condition was entirely due to cocaine. The plaintiff was formerly a strong, healthy man. Mr. Craven said that his assistant Munslow was a perfectly competent extractor of teeth and that he had extracted 487 teeth between Jan. 1st and August 17th. All these were "painless extracts," where cocaine was applied without a single complaint. Dr. Charles Pollard of Worcester said that cocaine was a proper drug to use in the extraction of teeth and to deaden the pain in the gums. He admitted that it was not a safe drug for an unqualified man to administer. The assistant, John S. Munslow, said that he had extracted teeth for over 20 years and had had frequent cases of "painless extraction." He only used 10 minims of cocaine in this particular case and never used more, and gave four injections. The plaintiff was in a very nervous and excited state. He had used the same glass for administering cocaine for the past year. He had always administered cocaine in the old-fashioned way and always should do so. Mr. Malven, chemist in the employ of Messrs. Parke, Davis and Co. manufacturing chemists, London, gave evidence as to the common use of the drug for extracting teeth all over the country and said he had often heard that cases of sickness arose from it. Mr. New said that the decision was of great importance to dental surgeons and others all over the country. The question was whether the administering of the drug for the purpose of "cheap painless extractions" was right and they wished the case to come before that court. His honour said that he came to the conclusion that the cocaine was negligently administered. He gave judgment for 10 guineas.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8317 births and 4312 deaths were registered during the week ending Oct. 17th The annual rate of mortality in these towns, which had been equal to 13·3 and 12·8 per 1000 in the two preceding weeks, rose again to 13·9 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these towns averaged 13·3 per 1000, and in London the mean rate in the same period did not exceed 12·1. The lowest annual death-rates in these towns last week were 3·4 in Hornsey, 5·0 in Leyton, 6·0 in King's Norton, and 6·9 in East Ham, all being suburban districts; the rates in the other towns ranged upwards, however, to 22·0 in Huddersfield, 22·4 in Swansea, 22·9 in Rochdale, and 27·4 in Bury. In London the death-rate during the week did not exceed 11·9 per 1000. The 4312 deaths from all causes in the 76 towns showed an increase of 333 upon the low number in the previous week, and included 613 which were referred to the principal epidemic diseases, against numbers declining from 1343 to 514 in the seven preceding weeks; of these 613 deaths, 430 resulted from diarrhœa, 55 from measles, 40 from "fever" (principally enteric), 32 from diphtheria, 31 from whooping-cough, and 25 from scarlet fever, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 2·0 per 1000, against a rate of 1·7 in each of the three preceding weeks; in London the death-rate from these diseases last week did not exceed 1·2. No death from any of these epidemic diseases was registered last week in Cardiff, Croydon, Hornsey, Newport, Ipswich, Bournemouth, Hanley, Hastings, or Great Yarmouth; whereas the annual death-rate therefrom ranged upwards in the other large towns to 6·5 in Grimsby, 6·6 in Warrington, and 8·2 in Rotherham. The deaths attributed to diarrhœa in the 76 towns, which had ranged in the eight preceding weeks from 1134 to 347, rose again last week under the influence of higher temperature to 430; the highest annual death-rates from this cause during last week were 3·7 in Aston Manor 3·8 in Hull, 4·0 in Middlesbrough, 4·4 in Preston, 4·6 in Stockport, and 6·5 in Grimsby. The deaths referred to "fever," which had been 35, 23, and 16 in the three preceding weeks, rose last week to 40, and exceeded the number returned in any previous week of this year; they included 11 in London, three in Liverpool, three in Leeds, and two each in Birmingham, Sheffield, and Hull. The 55 fatal cases of measles showed a further increase upon recent weekly numbers, and caused annual rates equal to 1·5 in Stockport and Warrington, 1·8 in Rochdale, and 2·5 in Rotherham. The 32 deaths from diphtheria exceeded the number in the previous week by four, and included 11 in London and two in Gateshead. The 31 fatal cases of whooping-cough showed a further decline, and were fewer than in any previous week of this year;

method of treatment is now nearly abandoned. Professor Tillmanns in his paper describes the technique of the operation and discusses the methods to be employed. When due care is taken harmful results are rare and in many cases multiple puncture has been performed without any ill effect. It seems clear that puncture of the brain will before long take a recognised place in surgery, both for diagnostic and therapeutic purposes, and Professor Tillmanns's article should give an impulse to the spread of the operation.

A POINT UNDER THE WORKMEN'S COMPENSATION ACT, 1906.

A CORRESPONDENT calls attention in a letter published on p. 1248 to a question which may arise at any time under the Workmen's Compensation Act when a nurse claims to have been injured by an accident in the performance of his or her duties and when there may be a difficulty in ascertaining who, if anyone, is liable to pay the compensation ordered by the Act. The question is not, of course, confined to occasions when nurses are injured but presents itself in many other phases of employment or alleged employment, and particularly when assistance of a more or less temporary nature is obtained by a person who is ready to pay for it but who does not thereby necessarily render himself the "employer." According to the definition in Section 13 of the Act, the word "employer" "includes any body of persons corporate or unincorporate and the legal personal representative of a deceased employer, and, where the services of a workman are temporarily lent or let on hire to another person by the person with whom the workman has entered into a contract of service or apprenticeship, the latter shall for the purposes of this Act be deemed to continue to be the employer of the workman whilst he is working for that other person." In connexion with private or domestic service instances can readily be suggested of the lending or letting on hire of workmen by employers who under this section do not thereby free themselves from liability to compensate for accidents occurring during the temporary hiring. The groom supplied by a livery stable or the waiter sent in by a refreshment contractor are examples, but in these, as in the case of the male attendant referred to by our correspondent, a claim may be made against the person for whom the work is actually done against which he will wish to defend himself, and sometimes it will be pressed all the more stubbornly because the legal employer has not insured himself and is not well provided with funds to meet his possible liability. How the law may be applicable to the instance quoted by "Cautious" it is not possible to say without further knowledge of the facts from which an inference might be drawn. Some nurses are under a contract of service to an "institution" from which they may be "sent," to quote his words, and in the case of others the institution may be merely an agency for finding employment, the contract for which may be made by the patient through them with the nurse. The description given by "Cautious" is consistent with either condition, and no doubt the question of liability under the Workmen's Compensation Act was not thought of by the attendant, by the institution, or by the patient until the injury was sustained by the first mentioned. In this particular case a solution occurs to us which may meet the difficulty, but as it is not suggested by our correspondent we merely advance it as a possible one. The patient, a chronic invalid usually under the care of a permanent attendant, may have insured the latter under the Act in such terms that his insurance company would be bound to compensate the temporary attendant on his behalf or to defend the claim. If the permanent attendant was away ill, or even if, though in the house, he was performing no duties, so that there was no liability possible with regard to him, the policy may be such as would cover his substitute. This, however, is a matter only affecting a particular case and the more general question as to who is to be looked to for compensation as a general rule by a nurse merits the serious consideration of patients of medical men who may be called on to find nurses for them, and last, but not least, of the nurses themselves. The most satisfactory position would appear to be obtained when the nurse and the nursing institution are at one in admitting a contract of service between them, and when the latter can furnish proof that it has insured the former. In the case of the nurse who is engaged by the patient under such conditions that the nurse becomes a "workman" and the patient an "employer" there should be insurance. We believe that many private individuals insure, not only in respect of their regular servants but also against the contingency of an accident happening to one only temporarily in their service. Such an insurance as this might be thought to apply to a nurse, but the premiums in respect of it are usually on a scale more consistent with the compensation of charwomen or caretakers engaged for a season than of nurses for the sick, and we have little doubt than when these are to be insured the insurance company would expect a special contract with premiums fixed after consideration of the extent not only of the pecuniary liability but of the peculiar risks involved.

THE TRYPSIN TREATMENT OF CANCER.

A LITTLE over a year ago in a leading article[1] we discussed the trypsin treatment of cancer at considerable length, and while keeping an open mind as to the possibility of its being proved of value concluded that no evidence of this had been produced. This treatment has been much extolled in the lay press, and as a result exaggerated hopes have been entertained by the public who to some extent have forced the use of trypsin on the profession. While admitting the advantage and even the necessity of instructing the public in some medical subjects, such as hygiene, we must deprecate any attempt to bring before them questions which are *sub judice* in the profession. Only evil can result from resort to such an incompetent tribunal. False hopes are aroused and when these are dashed to the ground persons ignorant of the difficulties of medical research too often are carried by the reaction to a disbelief in medical science and fall victims to quacks. The evidence which has accumulated since the publication of our article only confirms our conclusion. At the Seventh Congress of Scandinavian Surgeons Dr. N. R. Blegvad presented a report of ten cases of malignant growths treated by trypsin injections in Professor Rovsing's clinic at Copenhagen.[2] In only one case was there possible benefit (diminution of the quantity and fœtor of the discharge). In the *New York Medical Journal* of August 29th Dr. J. E. Weinstein has reported ten cases of carcinoma of the digestive organs in which there was no doubt as to the diagnosis and this treatment was tried. All the cases were treated by subcutaneous injections of trypsin and amylopsin. The amylopsin was used on the theory that the trypsin in acting on the cancer albumins produces poisonous compounds which the amylopsin digests. The preparation used (a glycerine extract of the pancreas) was prepared by Messrs. Fairchild Brothers and Foster. Some aching in the bones and backache were produced but therapeutic effects were entirely negative. There were some periods of improvement and at times the symptoms were temporarily lulled, but these were no more than occur spontaneously in any illness. Only one good result was observed—the soothing moral

Mackay, from the Yorkshire Dragoons (Queen's Own) Imperial Yeomanry, to be Surgeon-Major, with precedence as in the Imperial Yeomanry (dated April 1st, 1908). Yorkshire Hussars (Alexandra, Princess of Wales's Own): Surgeon-Captain Walter Henry Cheetham, from the Yorkshire Hussars (Alexandra, Princess of Wales's Own) Imperial Yeomanry, to be Surgeon-Captain, with precedence as in the Imperial Yeomanry (dated April 1st, 1908).

Royal Garrison Artillery.

Devonshire: Surgeon-Captain James P. S. Ward to be Surgeon-Major (dated April 6th, 1908).

Infantry.

7th Battalion, Northumberland Fusiliers: The undermentioned officers, from the 1st Volunteer Battalion, The Northumberland Fusiliers, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Major William Bertie Mackay and Surgeon-Lieutenant Charles George Maclagan. 5th and 6th Battalions, Royal Warwickshire Regiment: Surgeon-Major Richard Arthur Newton, from the 1st Volunteer Battalion, The Royal Warwickshire Regiment, to be Surgeon-Major, with precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Captain George Henry Ernest Bekenn, from the 1st Volunteer Battalion, The Royal Warwickshire Regiment, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 7th Battalion, Worcestershire Regiment: The undermentioned officers from the 1st Volunteer Battalion, The Worcestershire Regiment, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Major Joseph Robinson and Surgeon-Captain Bertram Addenbrooke. 8th Battalion, Worcestershire Regiment: Surgeon-Lieutenant Hubert Rodney Ross Fowler, from the 2nd Volunteer Battalion, The Worcestershire Regiment, to be Surgeon-Lieutenant, with precedence as in the Volunteer Force (dated April 1st, 1908). 5th Battalion (Cinque Ports), Royal Sussex Regiment: The undermentioned officers, from the 1st Cinque Ports Volunteer Rifle Corps, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Lieutenant Alfred Alexander and Surgeon-Lieutenant Peter Millar Waugh. 4th Battalion, Oxfordshire Light Infantry: The undermentioned officers, from the 2nd Volunteer Battalion, The Oxfordshire Light Infantry, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908): Surgeon-Major Julius Ottaway Sankey and Surgeon-Lieutenant Hubert de Burghe Dwyer. The Buckinghamshire Battalion, The Oxfordshire Light Infantry: Surgeon-Captain John Charles Baker, from the 1st Bucks Volunteer Rifle Corps, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). 26th Battalion, City of London Regiment (Honourable Artillery Company): The undermentioned officer from the Honourable Artillery Company of London is appointed to the battalion, with rank and precedence as in the Honourable Artillery Company of London (dated April 1st, 1908): Surgeon-Captain Edward Herbert Myddelton-Gavey.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Ayrshire and Galloway: Surgeon-Lieutenant-Colonel Robert Allan is granted the honorary rank of Surgeon-Colonel (dated March 30th, 1908). Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Robert Allan resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908).

Royal Engineers (Volunteers): 1st Lanarkshire: Surgeon-Captain John H. Teacher resigns his commission (dated March 31st, 1908).

Rifle: 6th Volunteer Battalion, The Royal Scots (Lothian Regiment): Surgeon-Lieutenant Harold S. Ballantyne resigns his commission (dated March 31st, 1908). 4th Volunteer Battalion, The Queen's (Royal West Surrey Regiment): The undermentioned officer resigns his commission (dated March 31st, 1908): Surgeon-Lieutenant Charles S. Palmer. 2nd (Berwickshire) Volunteer Battalion, The King's Own Scottish Borderers: Surgeon-Major Samuel Macvie resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908). The undermentioned officers resign their commissions (dated March 31st, 1908): Surgeon-Lieutenant Alexander J. Campbell and Surgeon-Lieutenant John Paxton. 5th (Deeside Highland) Volunteer Battalion, The Gordon Highlanders: The undermentioned Honorary Assistant Surgeons are retired, under the conditions of paragraph 103, Volunteer Regulations (dated March 31st, 1908): James McHardy and Alexander D. Keith.

Correspondence.

"Audi alteram partem."

SYPHILIS IN UGANDA.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an article in your issue of Oct. 3rd on "Syphilis in Uganda" and to certain statements therein contained as to the bearing of Christian teaching upon the tribal laws and customs of the Baganda and the disastrous consequences which, it is alleged, have resulted therefrom. May I be permitted to say that I disagree altogether with the assumption from which the conclusion is drawn.

The state of the case in my opinion is simply this. For ages the social restraints in the national life of the Baganda have been due entirely to the existence of a very complete system of feudal ties. The land was held on a service tenure terminable at the will of the king or chief. There was no fixity of tenure. Without such fixity of tenure it had come to be realised by those in authority that there could be no proper development of the country. Consequently the tendency of all legislation in Uganda in recent years has been towards the creation of a class of landed proprietors with the freehold of their lands. The result has been the abolition of the service tenure, the imposition of rent, and the complete break up of that feudal system which with all its restraints, wholesome and unwholesome, has yet, I believe, done good service in the making of Uganda. With this sweeping away of the feudal system has come in not liberty merely but licence, and the result we have stated for us in Colonel Lambkin's paper. Christianity, in my opinion, has had nothing whatever to do with these lamentable consequences. It is a fundamental principle of our work to interfere as little as possible with tribal laws and customs. The breakdown of the feudal system has been due not to Christian teaching—for Christian teaching had no controversy with it—but to Government legislation. In saying this I do not wish in the very least to reflect upon the policy of the administration, which I am sure has been actuated by the highest and best motives. But it is well, I think, that we should be clear in our minds in a case like this as to the causes to which such results as these set forth by Colonel Lambkin are traceable.

With regard to Christian teaching and its bearing on this great question may I quote the words of no less an authority than Sir Harry Johnston? In his great work, "The Uganda Protectorate," p. 642, he thus writes on the two points alluded to in your article—viz., the presumed moribund condition of the Baganda as a race and the introduction of monogamy: "If the Baganda are to be saved from dying out as a race —and I cannot but believe and hope they will—it will be entirely through the introduction of Christianity and the teaching of the missionaries, both Roman and Anglican. The introduction of monogamy as a universally recognised principle now amongst all people who desire to conform to mission teaching may be the salvation of Uganda, strange to say. The people through this teaching are now becoming ashamed of marrying girls who have led a bad life before marriage. The appreciation of female chastity is distinctly rising, while at the same time young men find debauchery no longer fashionable and endeavour to marry early and become the fathers of families. If ever a race needed a puritan revival to save it from extinction it is the Baganda, and if ever Christian missions did positive and unqualified good among a negro race this good has been accomplished in Uganda, where their teaching has turned the current of the more intelligent people's thoughts towards the physical advantages of chastity."

I think that after such an expression of opinion from

The Lancet Special Commission

ON

THE ORIGIN, MANUFACTURE, AND USES OF EXTRACT OF MEAT.

INTRODUCTORY.

FROM time to time we think it of interest to give an account of the processes involved in the manufacture of various foods which are well known to, and largely consumed by, the public. It is obviously impossible in very many instances for the medical profession or the public to ascertain for themselves the conditions under which these food products are manufactured, and yet it is very desirable that some assurance should be obtainable that not only are the foods themselves of excellent quality and in sound condition but that they are manufactured under the strictest demands of hygienic practice. It is, of course, open to our health authorities or the public itself to have samples of foods as they reach the consumer submitted to analysis, but this precaution, admirable as it is, leaves the question of the kind of sanitary *régime* under which they are prepared untouched. This is especially the case with imported foods of animal origin such as, for example, extracts of meat in various forms. We believe that the following account, which relates to the leading and oldest established industry of this type, which breeds and rears its own cattle under the personal supervision of its officials, and which had for its patron and founder a man who was a very distinguished physiologist and chemist in his time (1803–1873), will be read with interest. The materials for this account have been collected entirely by our Special Commissioner who was appointed to visit the very interesting scene of the operations concerned in the great industry early in the present year and in the height of the busy season. The facts are recorded exactly as he found them, and in the course of the article appears a number of analyses made in THE LANCET Laboratory of the products taken by him fresh from the factory and of samples collected at random in the open market at home. Finally, a section is added in which the dietetic value of these products is considered in the light of modern analytical methods.

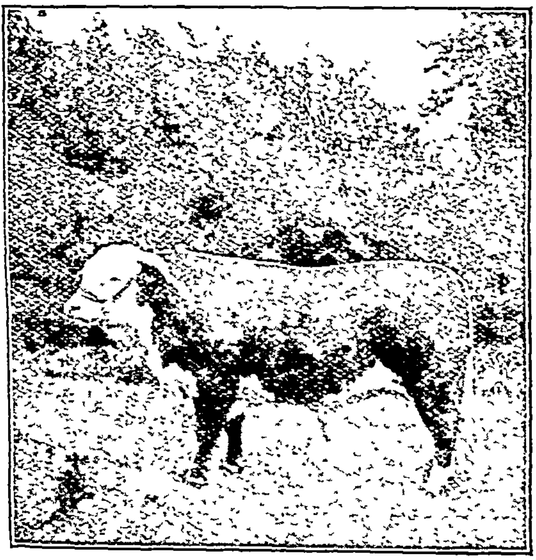

FIG. 1.—Pure-bred Hereford.

HISTORY AND PROGRESS OF THE MANUFACTURE OF MEAT EXTRACT.

Only those who have actually travelled over the vast grassy plains of Argentina, Uruguay, and Paraguay in South America can realise with any force at all how great have been the growth and progress of the cattle industry there since the year 1850 when Baron Justus von Liebig suggested the preparation of an extract of meat in countries where the breeding and rearing of cattle could be economically carried out. It was not, however, until 1865 that any serious attempt was made to put the suggestion into practice. "In 1862," wrote Baron Liebig, "I received a visit from Herr Giebert, an engineer of Hamburg, who had spent many years in South America and Uruguay where hundreds of thousands of sheep and oxen are killed solely for the hides and fat. He told me that directly he saw my account of the preparation of this extract he came to Munich with the intention of learning the process and then returning to South America in order to undertake its manufacture on a large scale. I therefore recommended Herr Giebert to Professor Pettenkofer, who willingly made him familiar with every detail of the process. He then returned to Uruguay in the summer of 1863, but owing to many difficulties which generally hinder the introduction and management of a new business, it was almost a year before he could actually commence the manufacture. Herr Giebert requested permission to call his extract by my name, which I granted, telling him, however, beforehand that if it contained the least trace of fat, which causes it to become rancid, or the gluey substance which the ordinary solid broth or consommé contains, which predisposes it to become mouldy, and entirely deprives the product of the unalterability of the pure extract, I should be the first to publicly assert its inferiority. In return Dr. Pettenkofer and myself promised to submit each to analysis free of cost and if found genuine to testify to the fact on condition that he would bring it into commerce at not more than a third of its present price. The arrangement, of course, relates only to the commencement of the importation, as the testimony of chemists will be no longer necessary when the public are once acquainted with the characteristics of the pure extract. Herr Giebert proposes to produce from five to six thousand pounds per month. The first sample, of about eighty pounds extract from beef and thirty pounds from mutton, arrived a few days ago in Munich, and we have the satisfaction of being able to say that for a product from the flesh of half-wild animals its quality is excellent; and we believe that the other condition—i.e., the price—will also meet our expectations."

The publication of this interesting statement in THE LANCET of Jan. 28th, 1865, drew some inquiries from our readers as to whether the extract could be obtained in quantity sufficient for practical purposes. On our own authority we replied in THE LANCET of March 18th, 1865, that "we believe that it is not at present a commercial article in this country but is likely to be so," and referred the writers to Baron Liebig himself. Later we received a letter from Mr. G. Van Abbott,[1] in which he wrote that "through the kindness of Baron Justus von Liebig I have arranged to have the first supply that can reach this country, and the moment it arrives I shall, with your permission, make it known through your columns." From a paragraph published in THE LANCET of April 29th, 1865, p. 467, it is made evident that Liebig's extractum carnis became for the first time a commercial commodity, for we then wrote: "We have learned that Mr. Van Abbott has just received a supply of the extractum carnis of Liebig, the merits of which have been of late so much discussed and a sample of which has been forwarded to us." These small consignments are now of historic interest, but they represented the beginnings of an industry which is at the present time of considerable importance in connexion with the problem of the food-supply of the world.

Liebig spoke of the first sample which he had received as being about 80 pounds, its quality, he added, being excellent, especially considering the fact that it was "a product from the flesh of half-wild animals." Nearly 50 years have come and gone since Liebig thus pronounced on the fruits of a pet project of his own, and, pleased as he was with the prospects of the comparatively new industry, he would have viewed with the liveliest satisfaction if he had lived its superstructure grown to its present enormous dimensions. Take, for example, some facts connected with the enterprising company to which he gave permission to bear his name. The Liebig

(2) infection, and (3) degeneration—diet seems to have the least to do with the decay of the teeth. Has anyone ever seen satisfactory results from wholemeal bread, "jaw drill," vegetable diet, or the score of other diet treatments? Dentists seldom look beyond their patients' teeth, so their theory that decay is due to neglect of the teeth is not worth much. Moreover, decay still goes on when the dentist has complete control.

I think it not unlikely that the improvement in dentistry has something to do with the increase of dental decay. When loss of teeth meant loss of health and life natural selection kept the teeth strong. Even a generation or two ago a woman with defective teeth had less chance of marriage, and so sexual selection also tended to preserve a disease-resisting type. But now the dentist has altered all this, and a complete set of false teeth is no detriment to a young woman; American women are even said to pride themselves on their gold stopping. I think you find the worst cases of infant dental caries in the offspring of mothers with decaying teeth, suggesting that decay may be due to direct infection. Infection acting upon degenerate teeth seems to me the only feasible theory, but the question can only be answered by the careful collection of facts.

I am, Sir, yours faithfully,

Silverton, Devon, Oct. 19th, 1908. O. CLAYTON JONES.

CARDIAC MOTION AS REVEALED BY THE VIVISECTION OF DISEASE.

To the Editor of THE LANCET.

SIR,—In the report of the proceedings of the Æsculapian Society which appeared in THE LANCET of Oct. 17th, the energetic secretary of the society whose succinct and accurate reports you regularly publish, slightly misunderstood two points in this instance, which, with your permission, I shall correct without delay, as the matters in question may be discussed again. In the first place, the sarcomatous invasion of the right auricle and ventricle very greatly restricted the contractility of those chambers, but as there was some uninvolved muscular tissue in both there may have been a very limited movement of both. In the next place the patient I showed was the case of thoracostomy for cardiac pain, an account of which you published in THE LANCET of July 4th, 1908, and while it was the first case operated upon for this cause it was not by any means the first case of thoracostomy for heart disease.

I am, Sir, yours faithfully,

ALEXANDER MORISON, M.D. Edin.

Upper Berkeley-street, Portman-square, W., Oct. 19th, 1908.

A POINT UNDER THE WORKMEN'S COMPENSATION ACT, 1906.

To the Editor of THE LANCET.

SIR,—The Workmen's Compensation Act (1906) has laid a very serious trap into which our patients may unwittingly fall. A patient of mine, a chronic invalid, quite helpless, sent for a male attendant from an institution to act as stop-gap during the illness of a permanent attendant. When the substitute had been in the house three days he ruptured some fibres of his diaphragm and has been invalided for over six months. The institution has no insurance for its men and the patient's insurance does not cover such a claim. Heavy claims are being made against my patient and he will probably have to disprove his liability in court, as the Act is so indefinite and so badly drafted as regards this point. It behoves medical men in the interests of their patients to ascertain what nursing "institutions" are insured and to recommend those only, and it would be to every one's interest that such concerns should announce in their advertisements the fact that they do insure their nurses.

I am, Sir, yours faithfully,

Oct. 16th, 1908. CAUTIOUS

THE WATER-SUPPLY OF ST. JUST (CORNWALL).—The St. Just Urban District Council, by its neglect to provide the town with an adequate water-supply, has exhausted the patience of the Cornwall County Council, which has complained to the Local Government Board and asked for an inquiry.

THE SANITARY DEFENCE OF THE HEDJAZ RAILWAY.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

(*Illustrated with Reproductions of Photographs taken by the Author.*)

III.[1]—MEDAINI-SALIH.

ABOUT two hours after leaving Tebuk our train passed through another rocky valley, known as the Zahr-el-Akhdar, and shortly after reached the "station" of Akhdar. There is no village here, nothing but the fortress-like station building. About two kilometres further on we stopped again, at the junction of two valleys; there is here a large reservoir with pump, and in the valley to the right (west) is the ancient *kala'at* of Akhdar. Here, also, there is no village, though close to the fort were a few black tents of some wandering Bedouins. Akhdar had been mentioned as a possible site for the future lazaret. There is a fairly large flat surface here, surrounded on all sides by hills. But the site would be in many ways inferior to that at Tebuk. We did not measure it, but it is certain that it would barely suffice (if, indeed, it did suffice) to contain all the cordons and buildings that it is proposed to put up in the first instance, and would not allow of expansion in the future, should such prove necessary. Moreover, being shut in by hills, there would be a lack of free circulation of air and the heat would be great.

Here, as in many other parts of the line, there is quite a considerable amount of desert herbage to break the monotony of unending sand and stones. In the Akhdar neighbourhood the colocynth plant is found in large quantities, creeping like a low-growing vine along the ground, and shedding its mottled gourds in all directions. Here also are found any number of annuloid fossils, to which the Bedouins give the unsavoury name of "Job's worms"; believing, it would seem, that it was in this desert that Job was finally cleansed and purged of his bodily ills. The water at Akhdar is said to be abundant and it proved to be of better quality than any other examined by the Commission. The specimen analysed was taken from the well in the *kala'at* and gave the following results. The water was colourless and clear and without smell; it contained 2·6 parts of chlorine as chlorides; 0·148 total nitrogen, of which 0·139 occurred as nitrates, 0·003 as free ammonia, and 0·006 as organic nitrogen; the oxygen consumed in the permanganate process in three hours at 27° C. was 0·0955; the total hardness was 14·21, and the permanent hardness after boiling 5·29. The total solids were 37. As before, all these figures represent parts per 100,000.

After a brief stay at Akhdar the Commission went on to Medaini-Salih, a night's journey further down the line. The approach to Medaini-Salih is through a remarkable bit of scenery. The line winds down through a gorge in the sandstone mountains, known to the Arabs as the Mubrakat-el-Nakà, or the valley of the "Camel-calf." The mountains in this portion of Arabia—not merely in the gorge—have been split up into the most fantastic forms: pinnacles, towers, and shapelessly monstrous objects of every kind rise abruptly from the sand, and it is really small wonder that the pilgrims have peopled this weird passage with evil spirits, whom they try to frighten away by loud cries as they pass through the gorge on their way to Medina. At the end of the gorge, but still surrounded by groups of the weird rocks, is the place known as Medaini-Salih—the "Cities of the Prophet Salih." The station is at the 955th kilometre from Damascus, and 347 north of Medina. It lies 820 metres above sea-level. There is no village of any kind here, and the only traces of the ancient "cities" are those wonderful Nabatæan monuments and inscriptions which must for ever be associated with the names of Doughty and Rénan. The old *kala'at* in which Mr. Doughty spent so many weary weeks still stands, with its reservoir by the side; but close by the railway has built its high water-tower and other of the station buildings almost surround the fort. The number and extent of these buildings show that this place is an important administrative centre on the line. They occupy the middle of a large, sandy plain dotted with tussocks of desert herbage, here more abundant never failing. Man has simply to provide this machine, keep it fed, clean, and within control. At present he is acquainted with no other method of converting grass into meat except through the channel of an animal organisation. He is bound to employ a physiological rather than a purely chemical process, and so the sentiment which is repugnant to the notion of breeding life ultimately to destroy life must for a while receive no consideration. Milk must be produced in the same way, for as yet no chemistry has been evolved which has enabled anyone to put the elements of milk together from grass so that it should be identical with the product of the lacteal gland. As with milk, so with meat; it can only be synthetically produced by the processes involved in animal life.

---

[1] Nos. I. and II. were published in THE LANCET of Sept. 26th, p. 971, and Oct. 10th, 1908, p. 1104, respectively.

We have already referred to the careful attention which the Liebig Company has given to the question of improving the breed of cattle, the greater part of which sooner or later and in some form or other are destined for human food. The results are satisfactory and they compensate amply for the expensiveness of such an admirable policy. The yield of products is not only increased but the quality of them is considerably improved—a matter of distinct importance when the supply of animal food materials is a principal object. When the total acreage of the Liebig farms is taken into account, coupled with the enormous herds feeding thereon, some conception of the grass-yielding value of the pasturage is gained. Apart from sheep the stock of cattle at the present time is about 250,000, which are distributed over 1,250,000 acres of grass. On this estimate the allotment to each animal is about five acres of pasturage. The average daily amount of grass consumed by one animal is 88 pounds; a herd of 250,000 would therefore consume per diem 22,000,000 pounds of grass, or approximately 10,000 tons. The yearly consumption of grass thus would mean not far short of 4,000,000 tons. The composition of pasture grass according to the average of a large number of analyses is as follows:—

	Per cent.
Water	80·00
Proteins with a small quantity of nitrogenous extractives*	3·50
Fat...	0·80
Carbohydrates	9·70
Fibre	4·00
Mineral salts	2·00
Total	100·00

* N × 6·25.

This means for a herd of 250,000 head of cattle per year a food yield in the form of grass of the following quantities of its individual solid constituents:—

	Tons.
Protein or flesh-forming substances	140,000
Fat	32,000
Carbohydrates	388,000
Fibre	160,000
Mineral salts	80,000
	800,000
Balance due to 80 per cent. water in grass	3,200,000
Total	4,000,000

These quantities are prodigious and they illustrate the increase which the land brings forth. Similarly, the annual amount of water consumed, based on the fact of one animal requiring 30 litres per day, would amount to 700,000,000 gallons per annum for the herd. These figures will convey some idea of the scale on which cattle farming is carried on in the Argentina and neighbouring states, but after all they refer only to the stock of one company, which, however, is the largest stock held, as it is the finest bred, by an individual concern. Altogether the cattle population of the Argentina is nearly 26,000,000 and in the Uruguay over 6,000,000 head. The Argentine, Uruguay, and Paraguay republics are, indeed, immense fodder-yielding tracts and the metamorphosis of grass proceeds steadily, surely, and uninterruptedly day by day on a colossal scale. There are occasions when the ordinary grass is supplemented by "alfalfa," a rich clover corresponding to our lucerne and containing a good proportion of nitrogenous food. It is well that every inch of this vast machinery is watched with care and that the best energy is devoted to the quality and purity of its products, for obviously the well-being and health of millions of consumers are concerned. Such is the case, at any rate, on the Liebig estates and in the factories according to the inquiries of our Commissioner, and to his account of the operations carried out on the *estancia* and in the factories of which he was an eye-witness during the season which closed last June.

THE ESTANCIA.

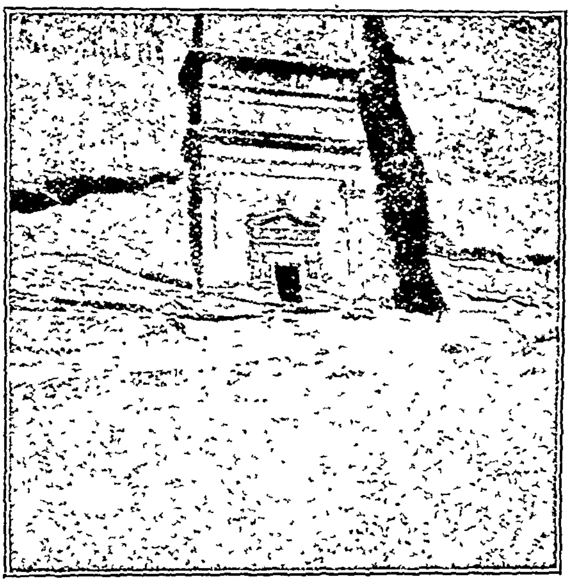
There is little to be said which can be regarded as of direct medical interest in connexion with the conduct of affairs on the *estancia*. As has already been stated, the *estancia* is a large grass farm presided over by the *estanciero* who is responsible to the company for the management and rearing of the cattle on the farm. Altogether the Liebig Company owns seven *estancias* in Uruguay, ten in Argentine, and nine in Paraguay. Besides these there are 10 others which are rented. Altogether the pasturage is spread over some 2000 square miles of country. The largest *estancias* represent an area each of from 74,000 to about 100,000 acres. In round numbers that is about 116 and 160 square miles in extent respectively. The area of some of the farms exceeds therefore that of the Isle of Wight, which is 145 square miles; others are equal in area to the whole county of London. Their topography and distribution will be seen from the large maps (Figs. 3 and 4). In Fig. 5 a diagram is given showing the area of the farms compared with Kent and Surrey. They are situated more or less on country which is contiguous to the Uruguay river which empties into the river Plate above Buenos Ayres. The soil is wonderfully fertile and the whole is an immense watershed. It has been said that the water poured into the Atlantic by the Parana and Uruguay rivers which culminate in the estuary known all over the world as the river Plate exceeds in volume that of the whole of the rivers of Europe put together. In Fig. 6 is seen a diagram comparing the volume of water in the Uruguay and Thames and also their respective lengths. The question of a pure and abundant water-supply, as well as a navigable water-way is, of course, of the first importance to the cattle-rearing industry. The existence of a wonderful water-supply and the fact of a seasonal rainfall being unfailing in the Argentine may be regarded as the chief factors which have contributed to the agricultural and farming success of the country. Later we shall deal with the question of the purity of the supply of water used in the factories of the Liebig Company, for our Commissioner secured various samples which have since been submitted to analysis.

Without entering into the precise details of *estancia* life (and they are full of interest to the student of natural history and of anthropography, as well as to the artist and the sociologist) it may be said shortly that the *estancias* supply a stock of cattle which are collected as these attain maturity and as occasion requires them for meeting the demands of the factories. The selection of the beasts for the purpose which is based upon their condition is an interesting and thrilling spectacle. The cattle scattered over an immense area of land divided into "potreros" or large fenced-in pasture tracts are brought together by the combined efforts of the gauchos, mounted peons, or peasants, until at length a "rodeo" is established—a collection of beasts, that is, averaging some thousands of head. The work of selection is then begun and it entails considerable skill and horsemanship to separate the animals judged to be ready for slaughter. The separation complete, the next step is to drive the animals to the factory. This may mean a score or even a hundred miles' journey through the country which in some parts, however, is relieved by railway transit. It is interesting to observe that on no account are the animals allowed to develop fatigue on this journey; they have ample rest in the "corrals" on the way and the daily drive never exceeds 15 miles. In Fig. 7 is seen a herd at rest. This precaution is of special importance, since it is well known that fatigue produces fatigue products which render the meat not only inferior in flavour but which may give it toxic qualities also. Besides which the animals, if unduly strained by a long journey, lose considerable weight.

THE FACTORY AND SLAUGHTER-HOUSES.

The killing season commences in January or at the end of December and ends in June. During this time the factories are in constant activity and as many as 1500 head of cattle a day are killed at each place. In 1907 the total number of animals slaughtered was 252,630 head. The Liebig factories are situated at Fray Bentos and at Colon, pictures of which appear in Figs. 8 and 9 respectively. The diameter and some 10 or 12 deep to the surface of water; it has rough masonry walls for the upper six feet, and then seems to be sunk in solid rock. In the other the masonry extends the whole way down; the bottom was of sand, with a little stagnant water in one corner. Not a few of the stones let into the walls bear inscriptions in the Nabatæan character, so that in all probability these wells, though vaguely ascribed to that race, date from a period a good deal more modern. Three similar wells are said to exist at the foot of the distant hills that bound the Medaini-Salih plain on the east. Up to the present the staff and workmen on the line have drunk the water from the station wells and it has not seriously affected their health. It has, however, a distinctly brackish taste, which is not surprising in view of the above figures, and we were told that later the railway authorities intend to import better water to Medaini-Salih either from El Oula (24 kilometres nearer Medina) or from Akhdar.

FIG. 10.



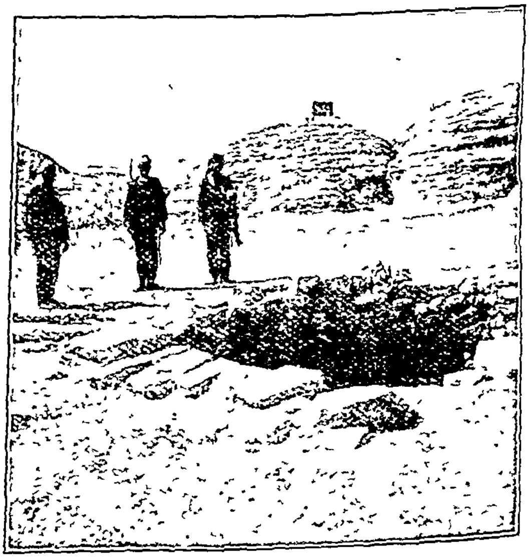
A Nabatæan monument at Medaini-Salih.

The stone found at Medaini-Salih is a sandstone of a rather friable character. It is not very suitable for permanent buildings and the railway imports a building stone of a better character from El Oula. Several truck-loads of this stone arrived while we were there. A passably good stone is also found as close as five kilometres from the station. But both these stones are said to be incomparably inferior to that found at Tebuk. The friable character of the Medaini-Salih stone is well seen in the neighbourhood of the Nabatæan monuments. Quite recently (last winter apparently) at the south end of the rocky hill known as the Kasr-el-Bint, which contains some of the best of these monuments, a large fragment of rock has fallen and been shattered to pieces at the foot of the hill, blocking up the façades of more than one of the tombs.

It is impossible to leave this brief description of what is perhaps one of the most remarkable spots in Arabia without some notice of these wonderful monuments of a forgotten civilisation, though their interest is archæological rather than in any sense medical. They have been once and for all so admirably described and illustrated by Mr. Doughty in the first volume of his "Arabia Deserta" (the original edition) that there is little left for later travellers to add. But it is impossible to stand before these stately façades (or "frontispieces," as he called them) without being profoundly impressed by their dignity, their number and size, and their "unexpectedness" in these weird desert solitudes. Many of them are 60 or 70 feet in height; yet the inner tomb chambers are curiously small in proportion to these great façades. There are many roughly hewn cells in each chamber where it may be supposed the coffins were placed; in nearly all are heaps of dead men's bones, mixed with fragments of pottery, fallen stones, bits of wood that may perhaps have formed parts of coffins, relics of a coarse cloth in which the bodies were presumably wrapped, and lumps of a resinous substance which may perhaps be some of the frankincense in which the ancient Nabatæans trafficked, or in which their bodies were rudely embalmed. Nothing is more remarkable than that no trace, save these tombs, remains of what, to judge by their number, must have been an important city. At their capital of Petra, on the other hand, there are, in addition to sepulchral monuments, innumerable façades of temples and public buildings of many kinds. But here at Medaini-Salih nothing is left but the tombs. And this is perhaps the more remarkable in that, with few exceptions, the Medaini-Salih façades are much better preserved than those at Petra, showing that the rock here, friable though it be, is more durable than that in the latter city.

The Commission did not go further than Medaini-Salih The rail head at that time was some way further on but it was impossible to proceed to it. At Medaini-Salih an escort of 50 men was provided for the Commission and it is probable that this precaution was far from being an empty form. On the day of our arrival there a serious attack was made on the head of the line and in the fight which followed some 40 Bedouins were said to have been killed. It would have been interesting to have gone on at least to El Oula, a large village or townlet in an oasis, and the most important centre in this region. There is said to be an abundant supply of water there and the water is reported of good quality; one spring alone is said to yield about 1000 tons a day. But the climate is said to be unhealthy and a form of oriental sore, akin to, or identical with, the Aleppo button, is so prevalent that practically every one suffers from it there. Perhaps it is not quite the same as the Aleppo button, as it only lasts some 30 or 35 days. It leaves pigmented scars; some people have two or more at the same time; they occur rarely on the face, more often on the exposed surface of one of the limbs. It is said to be unknown at Medaini-Salih and certainly does not occur at Tebuk.

FIG. 11



An ancient well, probably Nabatæan, at Medaini Salih.

As at other places along the line there are practically no meteorological records at Medaini-Salih. I have noted that at 1 P.M. on June 9th the thermometer stood at 39° C. in the shade and that at 4.30 P.M. it had risen to 41° C (105·8° F.). Meissner Pasha tells me that the extreme limits of temperature here are 45° C. (113° F.) in summer and − 7° C. (19·4° F.) in winter. Situated as Medaini-Salih is in a valley surrounded by rocky hills, the nights here are very hot in summer. Sandstorms of great severity are common; they are said to occur about once a fortnight; while they last they produce almost intolerable conditions Rain falls mostly in winter; sometimes in heavy downfalls, producing the inundations referred to in an earlier part of this article.

(To be concluded.)

former was the original factory of the Liebig Company. Fray Bentos is in Uruguay, on the east bank of the river of that name and about 100 miles from Buenos Ayres. Colon is about 80 miles higher up the same river, but is on the west bank, and is consequently in Argentina, in the department known as Entre Rios, a tract of country bounded on the east side by the Uruguay river and on the west and south by the Parana. The fact that the Colon factory was acquired comparatively recently, and after a considerable experience as to the requirements of the business had been accumulated at the earlier factory at Fray Bentos, necessarily rendered the former an advance on the latter in regard to accommodation, design, equipment, and machinery. In principle, however, the processes concerned in the slaughtering of the animals and their resolution into manifold products are substantially the same at both places. Before they reach the place of slaughter the cattle are carefully examined by the veterinary surgeon who is required to certify that only such animals are allowed to be killed as appear externally free from all disease. At Fray Bentos this work of inspection is carried out by an expert appointed by the company. At Colon this inspection is conducted by a representative of the Cattle Inspection Department of the Ministry of the Argentine Republic, who certifies each month that he has not allowed any animals to be killed that he did not find to be externally sound and free from all isease. The animals are killed by severing the spinal column at the back of the neck by means of a sharp two-edged knife shaped something like a bricklayer's trowel. The body is then conveyed quickly on a trolley which is placed over a gully. Here the throat is cut and the blood flows away down the gully. The blood is subsequently recovered and dried into a fine powder which is used as the basis of a valuable manure. After the animal has been so bled it is flayed. The carcass is then stripped of the organs, disembowelled, slung up, divided from end to end, and dressed. The scene can hardly be described as picturesque, especially when the rate of killing is often about two beasts per minute but the precautions taken to render it as inoffensive as possible are worthy of remark. The absolutely essential element which is required to keep such a slaughter-house clean and free from offence is here in superabundance. Hose-pipes delivering a constant and unstinting supply of the clean filtered water from the enormous river which flows by the factory are available everywhere and are continuously in use. The floors are tiled and fluted and set in such a way that flushing becomes a very effectual method of removing offensive materials. Even in the height of the season and in spite of the slaughter of, say, 1500 animals a day, the walls, floors, and surroundings present the cleanly appearance of a large model dairy. Thus, instead of a scene of carnage and shambles it is more like a well-appointed butcher's shop. Within ten minutes or so of its death the animal is divided by skilful butchers into the various parts and before the animal heat has dissipated. During these operations at the Fray Bentos (Uruguay) factories a careful inspection of the parts of the carcass is made by a staff of properly qualified men appointed by the company itself. These have to certify that a thorough examination of all the cattle killed was made and that only sound good meat was allowed to be converted into meat products and that any carcass or organ showing disease was disposed of in other ways. At the Colon (Argentine) factories, as already mentioned, an inspector is sent from the Ministry of Agriculture of the Argentine Republic who attends continuously and issues a monthly report. It is his duty to examine the carcasses of the cattle killed in the factories during each

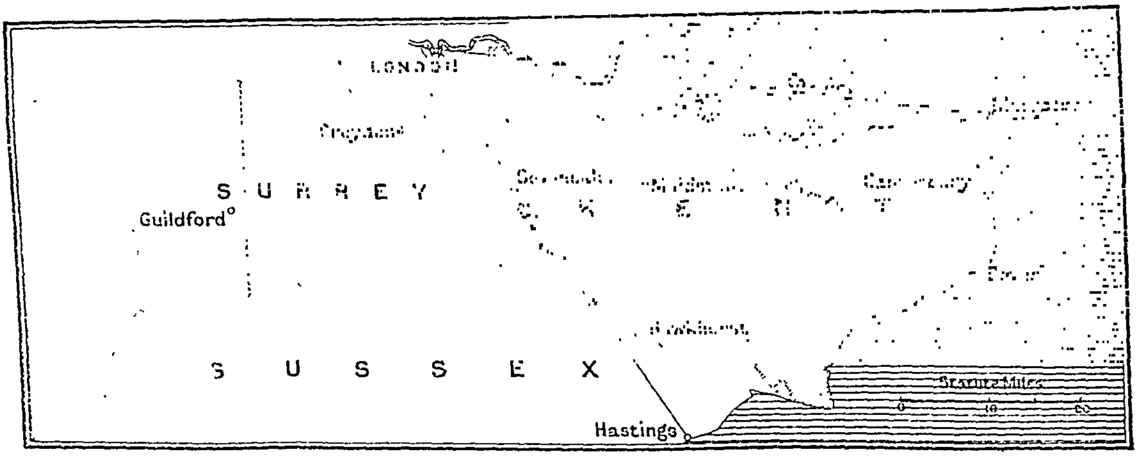

FIG. 5.—Map showing size of the Liebig Company's cattle farms compared with Kent and Surrey.

Glover was chosen because it was known that he would truly represent all that is best in the general body of medical practitioners, that he would be entirely single in his aims, that his opinions would be arrived at only after mature and impartial consideration, and that they would be expressed with courtesy and dignity. It was no secret to his friends that the results of Direct Representation have hitherto not been equal to the high hopes which he had for years entertained. But it may be very confidently affirmed that Dr. Glover's association with the General Medical Council was equally honourable to himself, grateful to his colleagues, and beneficial to the profession.

The movement for the establishment of the Metropolitan Hospital Sunday Fund was a second object in which he took the deepest interest, and for many years in our columns and elsewhere he urged the claims of this admirable institution. He was a member of the council of this Fund from its foundation to the close of his life. He took a prominent part in the work of the council and exercised a considerable influence upon its actions, while only so recently as Oct. 7th he attended a meeting of the general purposes committee. He was deeply interested in our hospitals from many points of view, but not the least from their being great voluntary charities, and year by year he did his utmost to urge the claims of Hospital Sunday upon all whom he could influence. At his instigation Sir Frederick Treves gave an address at Union Chapel, Islington, on Hospital Sunday last year, and this year he induced Sir Thomas Barlow to plead for hospitals before the same congregation. He believed that those who had spent much of their lives in the actual work of hospitals should be prepared to take their share in pleading for their support.

The third object in which he took a peculiar interest was the antiseptic system initiated by Lister. From the first he recognised the true scientific character of Lister's work and admired the sobriety and reserve with which he published his results. When too many were arrayed against the novel doctrines and their exponent, Dr. Glover lost no opportunity to advocate their soundness and to try to win for them an impartial acceptance. As an evidence of the worth of what he did we have before us a letter which Lord Lister wrote to Dr. Glover last year in acknowledging a letter from him on the occasion of Lord Lister's eightieth birthday. The letter gave unqualified pleasure to Dr. Glover and we feel that we are breaking no confidence in quoting from it these words: "In the early days of antiseptic work I had much reason for thankfulness to you, and you have always been a kind friend to me."

When the Clinical Society of London was founded in 1867 its aim appealed in a very special way to Dr. Glover, and he was elected to its membership in 1868, and for nearly 40 years he was a most constant attendant at its meetings. He often joined in the discussions, and his remarks were characterised by deep clinical insight, breadth of view, and a desire to bring into clear relief the practical issues at stake. He served on the council of the society and held office as a vice-president.

A man of Dr. Glover's mould could not find his work only in the practice of his profession and in the pursuit of literature. He touched life on every side, and life to him was the supreme interest. He was bound therefore to engage in the public affairs of the locality in which he lived and in the affairs of the nation. He was an earnest politician and exercised considerable influence upon the political convictions of his friends and neighbours. In all these matters his judgment of what was right and wise, and not the ties or interests of a party, determined his action. His conclusions were the outcome of careful study and bore the impress of that broad outlook and cheerful optimism that so eminently characterised his entire mental attitude. For several years Dr. Glover was Justice of the Peace for the county of Middlesex and acted as visiting justice to Holloway Prison, and as one of the licensing justices. He devoted himself with punctuality and the greatest carefulness to all the responsibilities of this important office, for he regarded it far more as a responsibility than as an honour. Dr. Glover came of a staunch Nonconformist stock and he remained loyal to these convictions throughout his long life. He was for many years a member of the congregation worshipping at Union Chapel, Islington, being an ardent admirer of the late Dr. Henry Allon, and of his successor, Dr. Harwood. He was, however, singularly free from all sectarian narrowness or bitterness; he took a special delight in the friendship of earnest men of other religious opinions than his own, and with that wide charity which was such a prominent feature in his character he rejoiced in the common faith and hope which lay beneath the distinctions of creeds and ceremonial.

In looking back upon this life, the fulness of which we have only been able to indicate very imperfectly, it is pleasant to remember that it was interrupted by no period of ill health, unclouded by any great family or personal sorrow, and was throughout its long and honourable course gladdened by the respect and affection of all with whom he was associated. He was permitted to live beyond the usual span, to see his children grow up and settled in life, to witness the accomplishment of most of the great purposes in which he had spent himself, and we think that he would himself have chosen that life should not extend far beyond his powers of service. Only this summer he handed over his practice at Highbury to his son and moved away to Hampstead, and it was while resuming for a short time the old practice, while the son was on his honeymoon, that the short fatal illness occurred. On Sunday, Oct. 11th, he was seized with pain in his chest; on Monday the pain recurred with greater severity and death appeared imminent, but he rallied, and on Wednesday he was so much better that hopes were entertained of his recovery, but in the evening he passed away with absolute suddenness, the cause of death being the rupture of an aortic aneurysm into the right pleural cavity. He was laid to rest in Hampstead Cemetery on Saturday last and on Sunday morning a memorial service was held at Union Chapel, Islington, with which he had been closely identified for so many years. There was a large congregation of his friends and patients and Dr. Harwood delivered an appreciative address which evidently struck a responsive chord in many of his audience.

Of such a life much might fitly be said; we must content ourselves with pointing out the striking example which it affords of the opportunity that a good man has for living a full and widely influential life while engaged in the practice of medicine. The association of literature with medicine has very many illustrations, but many another field of human interest afforded scope for Dr. Glover's energies. He was a very busy, active man, with a wonderful gift of being always occupied, and yet never in a hurry, intensely interested in what was for the moment engaging his attention, but never too absorbed to be sympathetic with any claim that presented itself. Strong in his own convictions, his love of truth and of justice enabled him to take a sympathetic interest in other views than his own; nor were his optimism and his intense confidence in the evolution of mankind a less striking and charming feature in his character. Able to appreciate and to rejoice in the deeds of the great men who have passed away, he ever had his eyes turned towards the dawn. Of him as of another long ago it may be said:—

> Ingenium cui nulla malum sententia suadet
> Ut faceret facinus levis aut malu'; doctu', fidelis,
> Suavis homo, facundu', suo contentu', beatus,
> Scitu', secunda loquens in tempore, commodu', verbum
> Paucum, multa tenens antiqua sepulta, vetustas
> Quem facit et mores veteresque novosque tenentem,
> Multorum veterum leges divomque hominumque;
> Prudenter, qui dicta loquive tacereve posset.

We append below personal appreciations from three of Dr. Glover's oldest friends and colleagues.

Sir John Tweedy writes to us as follows: "The death of Dr. Glover has given a shock of pained surprise to a large number of persons and I willingly accede to your request that I should attempt the melancholy task of writing a few words about his work, more particularly his connexion with medical journalism and politics. It is within a few months of thirty-seven years since I first became acquainted with Dr. Glover. He was then in the prime of life and at the zenith of his mental powers. He had already acquired an established position in medical practice and was an authority in most matters relating to medical politics and economics. His strong, earnest, and gracefully grave countenance was a truthful index to his mental and moral character. Always courteous but self-reliant he gained many a friend and disarmed many an opponent now by a kindly word, now by a sly touch of humour, now by a sharp and telling thrust former was the original factory of the Liebig Company. Fray Bentos is in Uruguay, on the east bank of the river of that name and about 100 miles from Buenos Ayres. Colon is about 80 miles higher up the same river, but is on the west bank, and is consequently in Argentina, in the department known as Entre Rios, a tract of country bounded on the east side by the Uruguay river and on the west and south by the Parana. The fact that the Colon factory was acquired comparatively recently, and after a considerable experience as to the requirements of the business had been accumulated at the earlier factory at Fray Bentos, necessarily rendered the former an advance on the latter in regard to accommodation, design, equipment, and machinery. In principle, however, the processes concerned in the slaughtering of the animals and their resolution into manifold products are substantially the same at both places. Before they reach the place of slaughter the cattle are carefully examined by the veterinary surgeon who is required to certify that only such animals are allowed to be killed as appear externally free from all disease. At Fray Bentos this work of inspection is carried out by an expert appointed by the company. At Colon this inspection is conducted by a representative of the Cattle Inspection Department of the Ministry of the Argentine Republic, who certifies each month that he has not allowed any animals to be killed that he did not find to be externally sound and free from all disease. The animals are killed by severing the spinal column at the back of the neck by means of a sharp two-edged knife shaped something like a bricklayer's trowel. The body is then conveyed quickly on a trolley which is placed over a gully. Here the throat is cut and the blood flows away down the gully. The blood is subsequently recovered and dried into a fine powder which is used as the basis of a valuable manure. After the animal has been so bled it is flayed. The carcass is then stripped of the organs, disembowelled, slung up, divided from end to end, and dressed. The scene can hardly be described as picturesque, especially when the rate of killing is often about two beasts per minute but the precautions taken to render it as inoffensive as possible are worthy of remark. The absolutely essential element which is required to keep such a slaughter-house clean and free from offence is here in superabundance. Hose-pipes delivering a constant and unstinting supply of the clean filtered water from the enormous river which flows by the factory are available everywhere and are continuously in use. The floors are tiled and fluted and set in such a way that flushing becomes a very effectual method of removing offensive materials. Even in the height of the season and in spite of the slaughter of, say, 1500 animals a day, the walls, floors, and surroundings present the cleanly appearance of a large model dairy. Thus, instead of a scene of carnage and shambles it is more like a well-appointed butcher's shop. Within ten minutes or so of its death the animal is divided by skilful butchers into the various parts and before the animal heat has dissipated. During these operations at the Fray Bentos (Uruguay) factories a careful inspection of the parts of the carcass is made by a staff of properly qualified men appointed by the company itself. These have to certify that a thorough examination of all the cattle killed was made and that only sound good meat was allowed to be converted into meat products and that any carcass or organ showing disease was disposed of in other ways. At the Colon (Argentine) factories, as already mentioned, an inspector is sent from the Ministry of Agriculture of the Argentine Republic who attends continuously and issues a monthly report. It is his duty to examine the carcasses of the cattle killed in the factories during each

by the Lord Mayor, Alderman Sayer, and an interesting municipal experiment has been commenced in particularly favourable circumstances. The situation has been well chosen and is particularly well adapted for its purpose. It is 800 feet above sea level; the chalets are placed on a southern slope and are protected on the east by a pine wood, they are built of brick, have slate roofs, are lined with plaster, and the floors are solid concrete to which a covering of linoleum is cemented. The windows open outwards and are arranged so that free through ventilation can be readily secured whilst rain and snow are excluded, and each room is provided with a small stove which is intended for use only in very inclement weather. It is proposed that each patient shall remain in the sanatorium not less than three months, during which he will not only be in favourable circumstances and under careful observation, but he will also learn lessons in sanitation, cleanliness, and ventilation which it is hoped he will inculcate into others when he returns home. There are baths in association with the chalets, but although they are both desirable and will no doubt prove very useful, sponge baths are also provided in the rooms, and the patients will be encouraged to use sponge baths and so cultivate a habit which they can easily continue when they return home.

The Hospital Saturday Fund.

At a meeting of the board of delegates held on Oct. 12th last it was stated that the amount received up to that date was £20,469, a total which exceeded the amount subscribed last year by £360. The committee recommended that £10,000 should be distributed amongst the Birmingham hospitals and certain other institutions on the same lines as last year, which means that the General Hospital will receive £3150, the Queen's Hospital £2100, the General Dispensary £1040, the Children's Hospital £800, the Women's Hospital £500, and other hospitals and nursing institutions sums varying from £400 to £10. The committee thinks that the result is very satisfactory, especially when the trade depression is taken into consideration, and it attributes the successful result to a growing appreciation of the work done by the fund and more especially an appreciation of that part of the work associated with the convalescent homes for men and women at Llandudno and the convalescent home for children at Great Barr. It may be inferred, therefore, that the hospitals need expect no increase in the amount of the fund devoted to their interests.

The Health of the City.

The death-rate, which reached 20 per 1000 during the week ending Sept. 18th, fell steadily after that date till the week ending Oct. 10th, when it was reduced to 11·8 per 1000; last week it rose slightly to 12·8 per 1000. During the same period the zymotic death-rate has varied from 1·9 to 1·6 per 1000, and the number of scarlet fever and diphtheria cases in the hospital has risen slowly but regularly. During the week ending Sept. 18th there were 274 scarlet fever patients and 63 diphtheria patients. During the following week the scarlet fever cases rose to 284 and the diphtheria cases to 66. During the two following weeks the number rose to 300 and 67 respectively, and last week there were 307 scarlet fever cases and 71 diphtheria cases. On the whole the health of the city is good and the outlook favourable.

The Birmingham Edinburgh University Graduates' Club.

The Birmingham Edinburgh University Graduates' Club had a very enjoyable evening on the occasion of their twelfth annual dinner which was held at the Grand Hotel on Oct. 15th. Professor A. Crum Brown was the guest of the club and in responding to the toast of the University of Edinburgh, proposed by the President, Dr. J. Douglas Stanley, he recalled many incidents of the period during which he occupied the chair of chemistry and told amusing tales of examiners and candidates. With the exception of Professor Crum Brown's response the speeches were few and short but the evening passed rapidly, enlivened by the humorous monologues of Dr. Sydney Partridge and Dr. Whaite and by the songs of Dr. G. H. Mounsey and Dr. Macleod Munro.

Medical Inspection in Warwickshire.

Dr. A. Bostock Hill, who believes that great advantages will eventually result from the medical inspection of school children, has arranged a series of conferences with head teachers. The first of the conferences was held at Erdington on Sept. 10th when Dr. Bostock Hill appealed for the help of the teachers and pointed out that although 12,000 children were to be examined this year the work could be done within the period of the school year. He said that the inspection was only a means to an end, the end being the amelioration of all the conditions which were inimical to the health of the children. In the discussion which followed, questions were asked regarding the circumstances which would necessitate the temporary closing of schools and Dr. Bostock Hill, in replying, stated that, in his opinion, schools should be closed when a reasonable proportion of children were affected with measles and during outbreaks of diphtheria. In most other cases closing was unnecessary and the exclusion of the sick children was sufficient.

An Effect of the Last Vaccination Legislation.

At a recent meeting of the King's Norton board of guardians it was reported that there was a steady increase in the birth-rate of the district, a diminution in the number of vaccinations, and a considerable increase in the number of exemption certificates. The increase in the number of exemption certificates is attributed to the fact that under the last Act the applicant can get an exemption from a magistrate without having to go before a court. Under the new Act the fees paid are considerably less than was the case previously and the result, so far as King's Norton is concerned, is a saving of £100 a quarter; this is, no doubt, considered to be a great advantage and it can only be hoped that the small part of the advantage due to the diminished number of vaccinations will not eventually prove to be very dearly bought.

Oct. 20th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Water-Supply: The Disposal of the City's Refuse.

AN idea of the gigantic dimensions of the Liverpool water-supply was given on Oct. 6th by the chairman of the water committee of the city council in quoting figures relating to the number of gallons distributed during the past 12 months and the population supplied. The measure of water in gallons supplied to over 1,000,000 people of Liverpool and neighbourhood from Rivington and Vyrnwy amounted to 11,600,000,000 gallons. This represents about 1,500,000 gallons a day increase. Never once were the resources taxed in the year, not even in the dry weather of the early summer. Liverpool could supply with ease a larger population and if the negotiations recently re-opened are brought to a successful issue Birkenhead will draw its supply from the same source. An interesting example of the progress and improvements made in disposing of the city's refuse also came to light. The corporation has just sold one of its mud hoppers for £1000, having no further use for its services. This was accounted for by the fact that whereas 88,000 tons of refuse were previously taken out to sea annually, only 40,000 tons are now so treated. The refuse destructors that have been built do the rest. This ought to make for less river pollution, but the aspect of the Seacombe and Egremont shore at low water scarcely verifies the suggestion.

Liverpool Select Vestry and the Treatment of Tuberculosis.

At a meeting of the select vestry held on Oct. 10th expression was given to the opinion that open-air treatment for consumptives, so far as it bears on the local operations of Poor-law guardians, is scarcely all that could be desired. The chairman of the workhouse committee reported that, as representative of the vestry at the recent Poor-law conference in Ulverston, he had spoken in opposition to the proposal that guardians should establish sanatoriums for consumptives, commending instead preventive work, such as that carried on by the Liverpool medical officer of health and his staff in the better housing of the people and the improvement of sanitary conditions. He added that the treatment of consumptives at the Heswall Sanatorium costs as much as £3 per week per patient and the vestry had had to pay sums of from £75 to £100 for patients whom it had sent to Heswall for treatment.

more or less syrupy liquid is placed in a special concentrator provided with a revolving worm and through which steam is passing. It is very essential if complete uniformity in regard to consistency and composition of the extract is aimed at that during the last stages of concentration the mass should be continually stirred. The treacly mass is then run off while hot into tin canisters of varying capacity and is ultimately dispatched to the distributing factories in Europe for subdivision into small parcels in the form in which the public receive it. It may be added that the extract is made and finished within three days of the death of the animal from the flesh of which it is derived. Such a proceeding must receive the entire approbation of all upholders of hygienic methods, for any time lost in the preparation of concentrated meat foods means time gained by the countless deteriorating agencies which find animal food a particularly congenial field wherein to multiply and to produce baneful products. Once, however, the concentration is secured extract of meat is, in its nearly solid state, no longer a culture medium. The process of extraction from beginning to end is subject to the supervisions of a chemist, and periodical analyses are made with the view of keeping the product constant in composition and quality. At both the Fray Bentos and Colon factories there are well-appointed chemical laboratories equipped with a staff of qualified analytical chemists. Before also the extract reaches the market from the distributing factories its composition and quality are certified by a scientific board. Amongst the scientific men serving in this capacity were Baron Liebig himself in 1865, his son and Professor Pettenkofer in 1872, and later Dr. Karl Voit, Dr. Max Rubner, Dr. Max Gruber, and Sir Henry Roscoe, the three last exercising their control at the present time. There is also accommodation given for biological work. It will be seen that the above processes effect the extraction of the uncoagulable portions of the meat which are soluble in water and that therefore the residue remaining consists of the fibrin and albumins in a more or less toughened state. The fat, as has already been stated, is skimmed off from time to time and filtration finally removes any traces left. It should be remarked, however, that the meat substance is in contact with hot water for some time and in the presence of the normal acids of muscular tissue. It follows that a certain amount of hydrolysis of the albumins takes place and that, therefore, to some extent part of the meat itself enters into the extract in the form chiefly of albumose and peptone. The extent to which this is the case will be seen from a number of analyses given below which were made in THE LANCET Laboratory. Samples for this purpose were taken by our Commissioner himself from both factories from the machine in which the final concentration is made.

TABLE I.—*Analysis of "Lemco" taken from the Liebig Companies Factories at Colon and Fray Bentos in South America.*

	Colon. Per cent.	Fray Bentos. Per cent.
Moisture	15·80	17·55
Mineral salts	26·37	19·38

Total protein	15·64	15·82	16·87	19·34	15·27	16·44	18·50	14·12	15·21	15·18
Creatine and creatinine	11·00	10·00	10·00	10·00	11·00	12·50	10·00	12 50	12·50	9·00
Insoluble matter (fibrin, albumin) ...	0·33	0·56	0·63	0·25	0·66	0·63	0·65	0·63	0·51	0·37
Sodium chloride	2·68	3·23	2·81	3·03	2·31	3·02	3·15	5·69	3·00	3·92
Phosphoric acid (P_2O_5)	6·70	5·37	5·41	4·55	5·31	5·52	6·11	3·06	6·30	6·13

A careful comparison of the figures in Tables II. and III. shows that the samples of "Lemco" purchased on the open market are practically identical in composition with the sample obtained directly from the distributing factory. The small differences which do exist are due to slightly varying amounts of water and are bound to occur owing to the hygroscopic nature of the extract. It is clear from these analyses number of pelvic deformities and other complications occur in its practice, frequently necessitating the performance of all the different kinds of obstetrical operations. The difficulty hitherto has always been that the accommodation and arrangements for enabling students to see the work were so meagre that full advantage could not be taken of the material for teaching purposes. The new hospital, which is up-to-date alike in structure and in appliances for treatment, will present a field for clinical instruction and post-graduate work that cannot be rivalled in the United Kingdom. Within a few months there will be opened a gynæcological department of at least 40 beds. By these provisions the University of Glasgow has been enabled at once to adopt the new conditions for the examination of students in clinical obstetrics. The establishment of a comfortable residence accommodating 15 students at the hospital makes it possible for the students to be called to all emergency cases, in addition to attendance at the regular daily clinique.

A New Hospital for Dunoon.

The Dunoon District Cottage Hospital, which has been built and equipped at a cost of £4000, was opened last week by Princess Louise, Duchess of Argyll. The hospital has an ideal site. The exposure is excellent with a commanding view of the firth. In the main block there are two wards with provision for 12 beds. An excellent operating theatre has also been provided and there is suitable accommodation for the staff.

Aberdeen Royal Infirmary: Gift from the Prince of Wales.

The Prince of Wales has by the hands of Professor D. W. Finlay sent a donation of £50 to the funds of the Aberdeen Royal Infirmary in recognition of the treatment of his late servant, Finlay Cameron. At a meeting of the board of directors held on Oct. 14th the desire was expressed that Professor Finlay would, in acknowledging the donation, convey to His Royal Highness the board's most grateful thanks for the gift, which was considered not only valuable in itself but calculated to stimulate liberality in others.

Aberdeen University Court: The Retirement of Professor Hamilton.

At a meeting of the Aberdeen University Court held on Oct. 13th Principal Lang referred to the retirement of Professor D. J. Hamilton. Reference had already been made at a previous meeting by Professor Hay and other members of the court to the very great distinction with which Professor Hamilton had occupied the chair of pathology since its foundation in 1882, and the great value of his service to the University and to science as a teacher of unsurpassed power and an investigator of the first rank. There could be only one feeling, and that a feeling of deep and sincere regret that he would no longer be one of their staff of teachers and that he had left a service which extended over 26 years and had shed a lustre, not only on his own department, not only on the medical school, not only on the four Scottish Universities, but on a very wide area beyond. They would always recollect their illustrious friend—the first professor of pathology in the University—his geniality of nature, and the loyalty of his coöperation in all affairs of the University that he so sincerely loved. Honours and sorrows were mingled together in the later years of Dr. Hamilton's occupancy of the chair.

Opening of the Winter Session at the University of Aberdeen: Impending Retirement of Professor A. Ogston.

The winter session of the University of Aberdeen opened on Oct. 13th. There was a large attendance at all the classes. In the surgery class Professor Ogston announced that he intended to retire at the end of the present academic year, saying that owing to the great advances which surgery was making the conduct of such a department was work for a young man who had all his life before him and not for him who had practically all his life behind him. He had been professor of surgery for 26 years and felt that the time had come when he should retire. Professor Ogston is a son of the late Professor Francis Ogston and graduated at the University of Aberdeen with highest honours. He studied at the Universities of Vienna, Prague, and Berlin, and later visited most of the leading medical schools of Europe. He commenced practice in Aberdeen in 1866, and until 1873 was assistant to his late father as professor of forensic medicine in the University. From 1868 to 1870 inclusive he was ophthalmic surgeon to the Aberdeen Royal Infirmary, and to 1874 aural surgeon. From 1873 to 1876 he was examiner for medical degrees in the University of Aberdeen. In 1882 he was appointed professor of surgery. Professor Ogston went to Egypt in 1885 and was in action near Hasbeen. He was awarded the Egyptian war medal and the Khedive's bronze star for the efficient assistance and personal bravery displayed during his stay in Egypt. Professor Ogston ranks among the greatest surgeons and operators both of this country and of the continent.

Semi-Jubilee of Dundee University College: New Physics and Electrical Laboratories.

The Semi-Jubilee of University College, Dundee, was signalised on Oct. 10th by the presence at the annual meeting of governors of the Right Hon. John Sinclair, M.P., Secretary of State for Scotland. Following this meeting there took place the ceremony of the laying of the foundation-stones of the new physics laboratory and of the new Peters electrical engineering laboratory. These buildings, the former of which will cost £12,500 and the latter £4000, are situated to the rear of the Union Mount property. The opening ceremony was performed by the Hon. Lady Marjory Sinclair in the presence of a large assemblage of the professoriate and students. At the close of the ceremony a reception was held in the College gymnasium.

Oct. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Sanitation of Dublin.

THE report of the public health committee on the state of the health and sanitation of Dublin was before the corporation at last week's meeting. Alderman Kelly, who moved the adoption of the report, called special attention to the gratifying fact that the death-rate was below the average of what it had been for a long period of years and that in last June it had fallen to the lowest figure on record. He took the opportunity of adding, "Dublin could never be in a satisfactory position with regard to its death-rate until the council applied attention to the removal of the city slums." Another member emphasised the fact that the death-rate, however low—comparatively—at present, still continued to be the highest in the kingdom. The corporation Bills which the citizens rejected a few months ago were opposed by Alderman Kelly and his party, who represented that the powers already possessed by the corporation were amply sufficient, if vigorously utilised, to eradicate all the evils under which the tenement house dweller of the city had suffered so long. Alderman J. C. McWalter, who had strongly supported these Bills, now demanded what their opponents had done to prove the truth of their assertions. Alderman Kelly, in replying, stated that while the burning question of the sanitary housing of the poor "presented great and grave difficulties" the "greatest and gravest of all was the interference of that council with sanitary officers."

Adulteration of Milk in Dublin.

The Recorder of Dublin has recently made a vigorous stand against the sale of adulterated milk in hearing an appeal from a sentence of six weeks' imprisonment passed by a police-court magistrate on Mr. H. Redhouse, dairy-keeper, for having sold milk which was adulterated with 10 per cent. of added water. It was shown that the defendant had several times previously been convicted of adulteration of milk and was actually fined £5 on the last occasion. An effort was made to lay the blame of the adulteration on a brother who managed the dairy farm. The appellant said that he had dismissed his brother from the management of his farm and promised that it would not occur again. The Recorder refused to "be taken in with talk of that kind from a man who had been convicted before and might have been fined £50 on the last occasion." He had previously remarked that the business of adulteration of milk meant simply the absolute murder of young children. Not only was the defective milk a cause of wasting in children, but it was a direct producer of intestinal and other diseases most detrimental to infant life. So far as he was concerned, he would use every effort to stamp out this fearful

Total nitrogen	10·30
Albumose	23·22
Peptone	*Nil.*
Total protein	23·22
Creatine and creatinine	5·00
Insoluble matters...	*Nil.*
Fat	Trace.
Sodium chloride	1·37
Phosphoric acid (P_2O_5)	4·00

The addition of this peptonised meat preparation to "Oxo" is therefore calculated to add considerably to its nutritive value, and as a matter of fact the analysis of "Nursing Oxo" gives the following results which show a considerable proportion of proteins:—

ANALYSIS OF "NURSING OXO."

	Per cent.
Moisture	23·27
Mineral salts	15·73
Organic matter	61·00
Total...	100·00
Total nitrogen	11·35
Albumose	20·28
Peptone	13·23
Total soluble protein	33·51
Insoluble matters	5·83
Creatine and creatinine	4·00
Sodium chloride	4·80
Phosphoric acid (P_2O_5)	4·38

It is directed that a teaspoonful of "Nursing Oxo" should be added to a breakfast-cupful of boiling water for the preparation of a nourishing beef-tea. A teaspoonful of "Nursing Oxo" weighs about half an ounce and the capacity of an ordinary breakfast-cup may be taken to be ten ounces, so that in preparing beef-tea with "Nursing Oxo" a 5 per cent. solution of the extract is enjoined to be made. Such a fluid has, according to the directions which we followed, the annexed percentage composition and it is interesting to place side by side with this the composition of beef-tea made with care from best rump steak:—

	Beef-tea made from fresh rump steak, 1 pound to 1 pint of water.		"Nursing Oxo," 1 part to 20 parts of water.
Water	97·46	....	95·65
Organic matters	2·01	....	3·42
Mineral salts	0·53	....	0·93
Total...	100·00	....	100·00
Total proteins	1·50	....	1·96
Extractives...	0·51	....	1·46

"Nursing Oxo" contains, therefore, at this extreme dilution more than one and a half times as much meat substances as are contained in beef-tea, an increase due to both proteins and extractives, but *more particularly* to the latter. It contains also the albumin and fibrin of beef which are absent in strained beef-tea. The strength of a cup of "Nursing Oxo" can, however, obviously be increased at will by adding more than a teaspoonful of the preparation to the breakfast-cup of hot water. Its preparation is both economical and simple.

MEAT EXTRACTS AND ALLIED PRODUCTS FROM A DIETETIC POINT OF VIEW.

Considerable controversy has centred round the question of the nutritive value of extract of meat and beef-tea and at the present time there is not a little division of opinion on the subject. There can be no doubt, at all events, that extract of meat is a most valuable adjunct to the dietary of both the healthy and the sick alike, but until recently little was known as to why this was so or as to the rôle which it plays as an undoubted aid to nutrition, if not, indeed, as a direct *contributor to it.* Whatever views may be held as to the nutritive value of the extractives of meat one thing is certain, and that is that the ingestion of meat from which these principles have been taken away places a very heavy task on the digestive organs. The extractives are, in fact, essential to the enjoyment and assimilation of the meat. The custom of preceding a meal with soup has, in other words, a strong physiological warranty. Schiff pointed out that the taking of soups, or what amounts to the same thing, extract of meat, stimulated the activity of the gastric glands and encouraged, therefore, in a remarkable way the assimilation and digestion of the solid constituents of the food which make up the balance of the meal. In his comparatively recent experiments Pawlow also demonstrated clearly that the extractives of meat are the most powerful exciters of gastric secretion that we possess and thus they serve the important dietetic purpose of assisting the appetite and of contributing to the digestion of food. Further than this, the extractives of meat as shown by Kobert are capable of removing the effects of muscular fatigue, enabling a tired muscle to become active again. This fact explains why solutions of beef extract exert recuperative effects in conditions of fatigue and act as a refreshing beverage. But meat extracts as a matter of chemical fact contain something besides extractives, though it must be admitted that these predominate. Still, modern analysis does show clearly enough that in the process of extraction a certain amount of hydrolytic action takes place and that therefore some of the albumin of the meat is converted into soluble proteins—viz., albumose and peptone—which have the same nutritive value as meat. In some instances these amount in extract of meat to nearly 20 per cent., or twice the quantity of creatinine, the chief base present. Now in the presence of the powerful gastric excitants which the extractives are admitted to be, apart from the fact that the albumoses and peptones are capable of playing the part in nutrition exhibited by proteins, a well-prepared beef extract must be, so far as its nutritive contents go, a very rapid and powerful restorative and nutrient. It has even been asserted that albumose and peptone do not simply diffuse through the intestinal wall but are taken up by the lining membrane and transformed by it as a result of the vital activity of its cells into serum albumin. The fact, moreover, that the extractives of meat are the most powerful excitants of gastric secretion that we possess justifies the addition as in "Oxo" of dry beef powder to the extract, for although it is true that this addition represents but a comparatively small measure of beef, yet the presence of extractives is calculated to secure the complete digestion of this amount. This assistance to assimilative power means that less meat is needed. As will be seen from the analytical results the average amount of *dry* beef powder added is from 5 to 6 per cent. Inasmuch as raw meat contains at least 75 per cent. of water the addition represents from 20 to 24 per cent. of raw meat. "Nursing Oxo" contains a similar addition of dry beef powder and besides about 25 per cent. of albumose, so that its nutrient value is considerable, especially having regard to the very material assistance given by the extractives to the digestive process. It will be readily understood also why milk or other comparatively tasteless food to which some extract of meat has been added should prove to be a powerful food and restorative. There is no constituent in milk which is calculated to excite the gastric secretions, and hence the addition of the stimulating extractives of beef is a decided dietetic advantage, especially for the sick and poorly nourished.

In discussing this stimulating effect of beef extractives on the digestive process it is interesting to compare the action of alcohol, and the comparison on the whole is an unfavourable one for alcohol, for while the risks attending the consumption of alcohol are well known there is comparatively no risk connected with the use of meat extract for dietetic purposes. Alcohol is, of course, a poison for obvious reasons, but it would be impossible to include meat extract in the same category, and yet in some ways it may be substituted for alcohol for similar dietetic objects. Alcohol is a true stimulant inasmuch as it spurs the heart to the *performance of more* work. The *stimulating* effect of meat extract, on the contrary, is *confined to the* digestive organs, and so the heart not being pushed to do more work *does not show those signs of* depression after partaking of meat extract which follow the imbibition of alcohol. In a word, the temporary benefit obtained by the stimulating effects of alcohol receives an undesirable compensation in the fact of cardiac depression ensuing. No such evil follows the use of meat extract, which, on the contrary, as has already been pointed out, helps to overcome fatigue died if he had held his hand. He laid down the general rule that all cases diagnosed as extra-uterine fœtation before the fifth month should be operated upon. After that time, on the other hand, a policy of "armed expectancy" might be adopted. M. Pozzi also differs from M. Albertin as regards colpotomy in septic cases because it is generally impossible to make sure as to whether a given case comes under that category. M. Pozzi said that he had often operated upon patients with a temperature of 40° C. and found nothing but simple clot. This interchange of opinions led to a brilliant debate between M. Delanny, M. Duret, M. Chavannaz, and M. Reynes. The treatment of absence of the vagina by plastic operations was also well discussed. M. Abadie sinks an artificial vagina between the bladder and the rectum, and lines it with skin grafts obtained by Thiersch's method, following a technique which he has seen Professor Forgue employ. All his grafts, except one, took capitally. M. Pozzi advocates that the artificial passage should be made as deep as possible. He cuts a plastic skin-flap to line its posterior wall only and directs the patient to wear permanently a perineal appliance provided with a rubber ball to maintain the patency of the vagina. M. Roux (Lausanne) lines the artificial passage with mucous membrane dissected from the labia minora and turned upwards, a plan which gives excellent results. M. Novaro has tried a plastic method, applying skin flaps to both anterior and posterior walls. M. Fournier has adopted the plan of slitting the labia minora. Progressive dilatation resulted finally in an artificial vagina of sufficient capacity. M. Péraire has attempted to re-establish continuity with the uterus and his patient lost a few drops of menstrual blood through a filiform passage. After making an artificial vagina by combining a simple incision with an auto-plastic turning up of flaps he used bougies to prevent the occurrence of stenosis. The operation was done nearly a year ago and the successful result has been maintained. Turning to general surgery again, M. Patel spoke on the treatment of gastric fistulas by jejunostomy. He treated a man aged 32 years successfully for a gastric fistula situated low down; the patient had entered hospital with all the signs of a subphrenic abscess, which was opened, and two days later the fistula was found. M. Patel did a lateral jejunostomy without delay with an immediate relief of the symptoms and later a cure of the fistula. Unfortunately the patient was suffering from cancer of the stomach and died six months later from cachexia.

The Treatment of Nephritis by Serum-Therapy.

M. Teissier of Lyons read before the Academy of Medicine on Oct. 6th a paper which is likely to attract a good deal of attention. It dealt with the treatment of nephritis. Continuing some experiments of Turbure, under the encouragement of results obtained from renal opotherapy (both by M. Renaut's plan of macerating whole kidneys of pigs and by using extracts of renal tissue), M. Teissier has injected patients suffering from nephritis with serum obtained from the blood of the renal vein and consequently containing the bodies elaborated by that organ. He employed the blood of a dog for this purpose and he is now using horse's blood which is notably less toxic. From 15 to 20 cubic centimetres of the serum have been injected every three, four, or five days beneath the skin of the abdomen of patients suffering from nephritis of widely varying types, some being in a state of pronounced uræmia. The effect has been rapid. The uræmia has cleared up, the coma and vomiting have ceased, and the albumin in the urine has diminished. These results are extremely interesting, for if they are confirmed they will form one of the most valuable therapeutic discoveries of the present time.

A Combined Surgical and Electrical Method of Treating Cancer.

At a meeting of the Hospitals' Medical Society on Oct. 9th M. Juge and M. Keating Hart showed a series of cancer patients who had undergone incomplete surgical treatment followed by the "*fulgurations*" treatment of Keating Hart. The patients were chosen from 40 people suffering from serious orificial, lingual, or mammary cancer, for whom simple surgical treatment would have been futile. The combined method gave remarkable results, for many of them have remained for two years or more without recurrence.

Oct. 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Moveable Cæcum.

Professor Wilms of the Basle surgical clinic, writing in the *Deutsche Medizinische Wochenschrift*, discusses the causes of so-called chronic appendicitis. The writer says that in about 20 per cent. of cases of chronic appendicitis no acute attack has preceded the chronic stage. In these cases the appendix when removed by operation proves, as a rule, to be healthy, and on microscopical examination nothing abnormal is found except some slight traces of appendicitis; these slight microscopical alterations do not explain the pain in the so-called "chronic appendicitis," and indeed in a great many cases the pain and tenderness over McBurney's point continue after the removal of the appendix. He has found that in many of these cases the symptoms are due not to appendicitis but to an abnormal length and mobility of the cæcum. This may be ascertained by palpation of the ileo-cæcal region. By this procedure the loose cæcum in a contracted state offers a tumour-like resistance and on superficial examination it may even be confounded with a moveable kidney. The cæcum when filled with fæces is, owing to its length, liable to traction, and this is of course painful. Professor Wilms has devised a method of treating this morbid state by fixing the loose cæcum. The results of the 40 cases operated upon hitherto are said to be very good, even in cases where a previous appendectomy had proved useless. The operation is easy and not more dangerous than appendectomy, which was always done at the same time as the fixation of the cæcum. The suggestion that the success may therefore be due not to the fixation of the cæcum but to the removal of the appendix is, however, not borne out. In order to test the value of his procedure in five of these cases he did an appendectomy without producing any improvement. Chronic appendicitis may of course be cured by appendectomy only; this is the case when the mesentery of the appendix is too short, so that the cæcum when full exerts traction on it. When the appendix is removed and thus separated from the mesentery the traction of course ceases, and the success of the operation in these cases is thus not due to the removal of an alleged inflamed appendix but to mechanical causes. A mobile cæcum may often be present without causing any trouble but this is also the case in moveable kidney in which the pain is caused by traction on the nerves. In some cases of moveable cæcum the pains may be cured by internal medication, especially by regulation of the diet and by regular purgation of the bowels; but if medicinal treatment is not efficacious within some weeks fixation of the cæcum should be done.

The Medical Academy of Dusseldorf.

As I have mentioned already in these columns medical academies have been established in Cologne and in Düsseldorf. The primary object of such institutions is that medical candidates after having passed the State examination may spend at the academy the year of practice required by recent regulations; the second purpose is to supply medical men with opportunities for post-graduate study. The academies of Cologne and Düsseldorf are supported exclusively by the municipal authorities of these cities but the State without any financial liability has an influential voice in the management of academical affairs, such as the appointment of the staff. The municipal authorities were induced to supply the necessary funds by the hope that a great number of students would be attracted to their town, and that well-to-do patients from far and near would come to consult the professors of the academy and to be received in the paying wards of the academical clinics. These hopes have proved erroneous; candidates for a medical qualification desiring to perform their statutory year of practice required by the regulations came in small numbers only to the academy, for they preferred other towns where they could comply with the regulations by acting as clinical clerks and dressers and where they receive for their work free board and residence and in certain cases even a small salary. The paying wards of the academical clinics were not much frequented because the medical men of the city and of the neighbourhood, who

Total nitrogen	10·30
Albumose	23·22
Peptone	*Nil.*
Total protein	23·22
Creatine and creatinine	5·00
Insoluble matters...	*Nil.*
Fat	Trace.
Sodium chloride	1·37
Phosphoric acid (P_2O_5)	4·00

The addition of this peptonised meat preparation to "Oxo" is therefore calculated to add considerably to its nutritive value, and as a matter of fact the analysis of "Nursing Oxo" gives the following results which show a considerable proportion of proteins :—

ANALYSIS OF "NURSING OXO."

	Per cent.
Moisture	23·27
Mineral salts	15·73
Organic matter	61·00
Total...	100·00
Total nitrogen	11·35
Albumose	20·28
Peptone	13·23
Total soluble protein	33·51
Insoluble matters	5·85
Creatine and creatinine	4·00
Sodium chloride	4·80
Phosphoric acid (P_2O_5)	4·38

It is directed that a teaspoonful of "Nursing Oxo" should be added to a breakfast-cupful of boiling water for the preparation of a nourishing beef-tea. A teaspoonful of "Nursing Oxo" weighs about half an ounce and the capacity of an ordinary breakfast-cup may be taken to be ten ounces, so that in preparing beef-tea with "Nursing Oxo" a 5 per cent. solution of the extract is enjoined to be made. Such a fluid has, according to the directions which we followed, the annexed percentage composition and it is interesting to place side by side with this the composition of beef-tea made with care from best rump steak :—

	Beef-tea made from fresh rump steak, 1 pound to 1 pint *of water.*		"Nursing Oxo," 1 part to 20 *parts of water.*
Water	97·46	....	95·65
Organic matters	2·01	....	3·42
Mineral salts	0·53	....	0·93
Total...	100·00	....	100·00
Total proteins	1·50	....	1·96
Extractives...	0·51	....	1·46

"Nursing Oxo" contains, therefore, at this *extreme* dilution more than one and a half times as much meat substances as are contained in beef-tea, an increase due to both proteins and extractives, but more particularly to the latter. It contains also the albumin and fibrin of beef which are absent in strained beef-tea. The strength of a cup of "Nursing Oxo" can, however, obviously be increased at will by adding more than a teaspoonful of the preparation to the breakfast-cup of hot water. Its preparation is both economical and simple.

MEAT EXTRACTS AND ALLIED PRODUCTS FROM A DIETETIC POINT OF VIEW.

Considerable controversy has centred round the question of the nutritive value of extract of meat and beef-tea and at the present time there is not a little division of opinion on the subject. There can be no doubt, at all events, that extract of meat is a most valuable adjunct to the dietary of both the healthy and the sick alike, but until recently little was known as to why this was so or as to the rôle which it plays as an undoubted aid to nutrition, if not, indeed, as a direct contributor to it. Whatever views may be held as to the nutritive value of the extractives of meat one thing is certain, and that is that the ingestion of meat from which these principles have been taken away places a very heavy task on the digestive organs. The extractives are, in fact, essential to the enjoyment and assimilation of the meat. The custom of preceding a meal with soup has, in other words, a strong physiological warranty. Schiff pointed out that the taking of soups, or what amounts to the same thing, extract of meat, stimulated the activity of the gastric glands and encouraged, therefore, in a remarkable way the assimilation and digestion of the solid constituents of the food which make up the balance of the meal. In his comparatively recent experiments Pawlow also demonstrated clearly that the extractives of meat are the most powerful exciters of gastric secretion that we possess and thus they serve the important dietetic purpose of assisting the appetite and of contributing to the digestion of food. Further than this, the extractives of meat as shown by Kobert are capable of removing the effects of muscular fatigue, enabling a tired muscle to become active again. This fact explains why solutions of beef extract exert recuperative effects in conditions of fatigue and act as a refreshing beverage. But meat extracts as a matter of chemical fact contain something besides extractives, though it must be admitted that these predominate. Still, modern analysis does show clearly enough that in the process of extraction a certain amount of hydrolytic action takes place and that therefore some of the albumin of the meat is converted into soluble proteins—viz., albumose and peptone—which have the same nutritive value as meat. In some instances these amount in extract of meat to nearly 20 per cent., or twice the quantity of creatinine, the chief base present. Now in the presence of the powerful gastric excitants which the extractives are admitted to be, apart from the fact that the albumoses and peptones are capable of playing the part in nutrition exhibited by proteins, a well-prepared beef extract must be, so far as its nutritive contents go, a very rapid and powerful restorative and nutrient. It has even been asserted that albumose and peptone do not simply diffuse through the intestinal wall but are taken up by the lining membrane and transformed by it as a result of the vital activity of its cells into serum albumin. The fact, moreover, that the extractives of meat are the most powerful excitants of gastric secretion that we possess justifies the addition as in "Oxo" of dry beef powder to the extract, for although it is true that this addition represents but a comparatively small measure of beef, yet the presence of extractives is calculated to secure the complete digestion of this amount. This assistance to assimilative power means that less meat is needed. As will be seen from the analytical results the average amount of *dry* beef powder added is from 5 to 6 per cent. Inasmuch as raw meat contains at least 75 per cent. of water the addition represents from 20 to 24 per cent. of raw meat. "Nursing Oxo" contains a similar addition of dry beef powder and besides about 25 per cent. of albumose, so that its nutrient value is considerable, especially having regard to the very material assistance given by the extractives to the digestive process. It will be readily understood also why milk or other comparatively tasteless food to which some extract of meat has been added should prove to be a powerful food and restorative. There is no constituent in milk which is calculated to excite the gastric secretions, and hence the addition of the stimulating extractives of beef is a decided dietetic advantage, especially for the sick and poorly nourished.

In discussing this stimulating effect of beef extractives on the digestive process it is interesting to compare the action of alcohol, and the comparison on the whole is an unfavourable one for alcohol, for while the risks attending the consumption of alcohol are well known there is comparatively no risk connected with the use of meat extract for dietetic purposes. Alcohol is, of course, a poison for obvious reasons, but it would be impossible to include meat extract in the same category, and yet in some ways it may be substituted for alcohol for similar dietetic objects. Alcohol is a true stimulant inasmuch as it spurs the heart to the performance of more work. The stimulating effect of meat extract, on the contrary, is confined to the digestive organs, and so the heart not being pushed to do more work does not show those signs of depression after partaking of meat extract which follow the imbibition of alcohol. In a word, the temporary benefit obtained by the stimulating effects of alcohol receives an undesirable compensation in the fact of cardiac depression ensuing. No such evil follows the use of meat extract, which, on the contrary, as has already been pointed out, helps to overcome fatigue of Pharmacognosis. Dr. Thomas v. Resck has been appointed Director of the Wieden Hospital.—*Würzburg:* Dr. Burckhardt, *privat-docent* of Surgery, has been granted the title of Extraordinary Professor.

WESTMINSTER HOSPITAL.—Entrance scholarships have been awarded at the Westminster Hospital Medical School as follows: R. C. C. Clay, Epsom scholarship, value 120 guineas; W. G. Shakespeare, first scholarship in Arts, value £60; D. M. Connan, natural science scholarship, value £60; J. W. Ebden, second scholarship in Arts, value £40; and J. Lloyd, second science scholarship, value £40.

GIFT OF A CONVALESCENT HOME.—Mr. G. P. Shepherd of Keymer, Sussex, has given a sum of £10,000 to build and to endow a convalescent home at Worthing for patients from the Surrey County Hospital, Guildford. A site for the building at the east end of the Parade, with its main frontage to the Brighton-road, has been purchased by public subscription at a cost of £650. There will be accommodation for six female and four male patients, and all the dormitories will open upon balconies overlooking the sea.

PRESENTATIONS TO A MEDICAL MAN.—Dr. A. E. Brindley, the newly appointed medical officer of health of the borough of Derby, has been the recipient of some presentations at Bury, Lancashire, on relinquishing his appointment in that town. The staff of the municipal cleansing department gave a tantalus spirit frame "as a mark of esteem and respect." At the request of the carters at the town's yard the Shire Horse Society's prize won by corporation horses at the recent Prestwich agricultural show was handed over to Dr. Brindley, and the chief officials of the corporation and the staff of the health department presented him with a dressing-case and a barometer. In addition he received handsome presents from the staff of the Florence Nightingale Hospital for Infectious Diseases and from the staff of the Ainsworth small-pox isolation hospital, of which he was medical superintendent.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A party of French medical men, connected with the Société d'Hydrologie de Paris, who are interested in balneology and climatology, are paying a visit to England in connexion with the Voyages d'Etudes Médicales, and have been invited to attend this society's ordinary meeting on Oct. 29th. It has been arranged that the Fellows of the Society (who may bring guests, including ladies) shall dine on the same evening, at 7.30 P.M., with their French colleagues (some of whom will be accompanied by ladies), at the Great Central Hotel, Marylebone-road, each one paying for his own party. The charge for dinner will be 5*s*., exclusive of wine. It is thought that there will be a large attendance of Fellows. Notice of intention to dine should be sent to the London secretary, Dr. S. P. Sunderland, 11, Cavendish-place, London, W., the day before the meeting if possible.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—At the annual general meeting of the Royal Academy of Medicine, held at the Royal College of Physicians on Oct. 9th, the following officers and councils were elected for the coming year:—President of the Academy: J. Magee Finny. General Secretary: James Craig. Secretary for Foreign Correspondence: Sir John Moore. Medical Section:—President: Walter G. Smith. Council: J. B. Coleman, H. C. Drury, T. P. C. Kirkpatrick, J. A. Matson, T. G. Moorhead, J. F. O'Carroll, G. Peacocke, F. C. Purser, E. J. Watson, and W. A. Winter. Surgical Section:—President: John Lentaigne, P.R.C.S. Council: C. A. Ball, Alexander Blaney, Sir A. Chance, W. S. Haughton, R. C. B. Maunsell, Seton Pringle, Sir H. Swanzy, E. H. Taylor, W. Taylor, and W. I. de C. Wheeler. Obstetrical Section:—President: E. H. Tweedy. Council: Gibbon FitzGibbon, M. J. Gibson, J. H. R. Glenn, A. N. Holmes, A. J. Horne, H. Jellett, F. W. Kidd, R. D. Purefoy, J. Spencer Sheill, and T. H. Wilson. Pathological Section:—President: A. R. Parsons. Council: A. H. Benson, H. C. Earl, L. G. Gunn, W. G. Harvey, H. C. Mooney, J. F. O'Carroll, A. C. O'Sullivan, R. J. Rowlette, J. A. Scott, and A. H. White. Section of Anatomy and Physiology:—President: T. H. Milroy, Council: A. F. Dixon, A. Fraser, H. M. Johnston, E. L'E. Ledwich, and E. P. McLoughlin. Section of State Medicine:—President: W. R. Dawson. Council: A. E. Boyd, T. Donnelly, T. P. C. Kirkpatrick, E. J. McWeeney, J. A. Matson, and W. A. Winter. Resolutions of condolence were passed in reference to the deaths of Sir John T. Banks, K.C.B., Sir Arthur V. Macan, and Dr. Conolly Norman, which occurred since the last annual meeting of the Academy.

THE LATE DR. EMILY E. EBERLE OF CLIFTON.—As a memorial to the late Dr. Emily Eberle a free bed bearing her name is to be placed at the Private Hospital for Women, Berkeley-square, Clifton.

DAMAGES FOR PTOMAINE POISONING.—At Abergavenny (Monmouthshire) police court last week a local grocer was awarded £30 damages against a Cardiff tradesman. The damages were claimed for nursing charges and loss of custom during illness alleged to have been caused by ptomaine poisoning brought about by eating bacon bought from defendant. Dr. T. E. Lloyd, who gave evidence, stated that he ordered the bacon to be destroyed. When he examined it he found that it had been cured with boric acid.

INFANTS' HEALTH EXHIBITION.—The Infants' Health Exhibition was formally opened by H.R.H. the Duchess of Albany at the Institute of Hygiene buildings in Devonshire-street, London, W., on Oct. 19th, and many members of the medical profession, as well as a number of ladies specially interested in the welfare of children, were present. Sir William Bennett, the President, after a few introductory remarks, said that the Incorporated Institute of Hygiene commenced its career with the object of promoting the study and practice of personal and domestic hygiene—that is to say, the hygiene of the family and the home. The preservation of life at all costs, no matter how valueless the life may seem to be, was a common instinct of civilised humanity, and, indeed, was an ethical necessity in the established methods of modern civilisation. At the same time it must be obvious to the meanest capacity that in preserving the lives of certain physically or mentally defective infants—in other words, in preserving the unfit—the community must be taking up a burden which, apart from its purely humanitarian aspect, had no corresponding advantage and might indeed be a danger, a fact appreciated to the full extent by highly civilised people in the distant past and by some barbarian races at the present time. In the struggle for supremacy, when the crisis came, as it must do soon or late, it was as sure as sure could be that the nation which was individually and collectively the most healthy physically and morally would survive, and since the child was father to the man it was a logical sequence that the nation which reared the healthiest children would have at its back the strongest men and women. H.R.H. the Duchess of Albany, in formally declaring the exhibition open, pulled a silk ribbon and drew the curtains back from the two entrances in the reception room leading to the Infants' Health Exhibition.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—The following Entrance Scholarships in Arts have been awarded for the session 1908–09: First Buxton Scholarship, Mr. Cecil Bluett (private instruction); Second Buxton Scholarship, Mr. Alma Percy Ford (Mercer's School).—A course of eight lectures on "The Circulation in Man" was commenced on Oct. 16th in the Physiological Theatre of the London Hospital Medical College and will be continued on Oct. 23rd and the six following Fridays at the same hour. They will be free to all students of the University of London. Dr. Martin Flack gave the first lecture and is the lecturer for Oct. 23rd. The next four lectures will be given by Dr. Thomas Lewis, and the last two by Dr. Leonard E. Hill. The syllabus is as follows:—Lecture I.: The histological structure of heart muscle; the distribution of ganglion cells and nerve fibres; the sino-auricular node; the auriculo-ventricular bundle and its connexions. II.: The fundamental properties of cardiac muscle; the coördination and movements of different parts of the heart. III.: A brief history of our knowledge of the venous pulse in animals and man; the anatomy of the jugular veins and apparatus employed in taking venous curves; general constitution of the venous pulse and the relation of venous records to other methods of examining the heart; the detailed analysis of the normal venous pulse. IV.: The clinical interpretation of venous pulse. V.: Heart-block. VI.: The causation of the they caused, however, annual rates in the week equal to 1·5 in West Bromwich, 1·6 in Rotherham, and 2·9 in Stockton-on-Tees. Of the 25 deaths from scarlet fever, a decline of 18 from the number in the previous week, seven occurred in London and its suburban districts, three in Liverpool, four in Manchester and Salford, and two in Birmingham. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased in the six preceding weeks from 2855 to 3742, had further increased to 3755 on Saturday, Oct. 17th; the number of new cases of this disease admitted to these hospitals during the week under notice were 502, against 576 and 550 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 159 and 156 in the two preceding weeks, rose again to 159 in the week under notice, but were 47 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 31, or 0·7 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death during last week were again duly certified in Manchester, Leeds, Sheffield, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 53 other smaller towns; the 31 uncertified causes of death included six in Birmingham, four in Liverpool, four in Gateshead, three both in St. Helens and Nottingham, and two in Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·4 and 13·6 per 1000 in the two preceding weeks, declined again to 12·4 in the week ending Oct. 17th. During the first three weeks of the current quarter the annual death-rate in these eight towns averaged 13·1 per 1000, and was 0·2 below the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 7·4 and 8·0 in Perth and Greenock, to 13·8 in Glasgow and 14·4 in Paisley. The 436 deaths in the eight towns showed a decline of 45 from the number in the previous week, and included 58 which were referred to the principal epidemic diseases, against numbers declining from 107 to 55 in the eight preceding weeks; of these 58 deaths, 33 resulted from diarrhœa, 17 from whooping-cough, three from diphtheria, two from measles, two from scarlet fever, and one from "fever," but not one from small-pox. These 58 deaths were equal to an annual rate of 1·6 per 1000, which was 0·4 below the mean rate from the same diseases in the 76 large English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had declined in the six preceding weeks from 64 to 28, rose again to 33 in the week under notice; 18 occurred in Glasgow, seven in Dundee, four in Edinburgh, and two in Greenock. The 17 fatal cases of whooping-cough showed an increase of eight upon the number in the previous week, and included 11 in Glasgow, three in Dundee, and two in Greenock. The three deaths from diphtheria were fewer by eight than those in the previous week, and were all returned in Glasgow. The deaths referred to "fever," which had been five in each of the two preceding weeks, declined to one last week, which occurred in Glasgow, and was certified as cerebro-spinal fever. The fatal cases both of measles and scarlet fever were again below the average. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 61 and 62 in the two previous weeks, declined last week to 58, and were 15 below the number returned in these towns in the corresponding week of last year. The causes of 15, or 3·4 per cent., of the deaths registered during the week in the eight towns were not stated or not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·7 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 20·8, 18·0, and 16·4 per 1000 in the three preceding weeks, rose again to 17·4 in the week ending Oct. 17th. During the first three weeks of the current quarter the death-rate in the city averaged 17·3 per 1000; the mean rate during the same period did not exceed 12·1 in London and 12·4 in Edinburgh. The 132 deaths of Dublin residents during the week under notice showed an increase of eight upon the numbers in the previous week, and included 13 which were referred to the principal zymotic diseases, against 17 and 19 in the two preceding weeks. These 13 deaths were equal to an annual rate of 1·7 per 1000; the rate during the same week from these diseases did not exceed 1·2 in London and 0·7 in Edinburgh. Of the 17 deaths from these epidemic diseases in Dublin last week, five resulted from diarrhœa, three from "fever," two from measles, and one each from scarlet fever, diphtheria, and whooping-cough, but not one from small-pox. The deaths attributed to diarrhœa have steadily declined in the past nine weeks from 39 to five. The three deaths referred to "fever" were one below the number returned in each of the two preceding weeks; and the two fatal cases of measles also showed a decline. The 132 deaths from all causes during the week included 26 of infants under one year of age and 39 of persons aged upwards of 60 years; the deaths of elderly persons exceeded the number in the previous week by 14. One inquest case and no death from violence was registered; and 61, or 46·2 per cent., of the deaths occurred in public institutions. The causes of four, or 3·0 per cent., of the deaths registered during the week in Dublin were not certified; in London the causes of all but one of the 1092 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was 5·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Surgeon: H. M. Braithwaite to the *Pembroke*, additional, to be lent to the *Attentive*, temporary.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles G. D. Mosse retires on retired pay (dated Oct. 17th, 1908).

Major Harold S. Peeke is placed on temporary half-pay on account of ill-health (dated Oct. 18th, 1908).

ROYAL ARMY MEDICAL CORPS (MILITIA).

An official notice in the *London Gazette*, dated Oct. 20th, 1908, states that His Majesty the King has been graciously pleased to approve of the disbandment of the Royal Army Medical Corps (Militia).

MILITIA.

Infantry: 8th Battalion, The King's Royal Rifle Corps: Surgeon-Lieutenant-Colonel Edward A. Rawson retires, with permission to retain his rank and to wear the prescribed uniform (dated Sept. 27th, 1908).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Edward A. Rawson having reached the prescribed limit of age ceases to belong to the Army Medical Reserve of Officers (dated Sept. 27th, 1908).

TERRITORIAL FORCE.

Yeomanry.

Berkshire (Hungerford): Surgeon-Lieutenant Maurice Were Coleman, from the Berks Imperial Yeomanry, to be Surgeon-Lieutenant, with precedence as in the Imperial Yeomanry (dated April 1st, 1908). Hampshire (Carabiniers): Surgeon-Captain Henry Augustus Ahrens, from the Hampshire (Carabiniers) Imperial Yeomanry, to be Surgeon-Captain, with precedence as in the Imperial Yeomanry (dated April 1st, 1908). West Kent (Queen's Own): The undermentioned officer from the West Kent (Queen's Own) Imperial Yeomanry is appointed to the regiment, with rank and precedence as in the Imperial Yeomanry (dated April 1st, 1908): Surgeon-Captain Gardiner William Trouton. Northumberland: The undermentioned officers from the Northumberland (Hussars) Imperial Yeomanry are appointed to the regiment, with rank and precedence as in the Imperial Yeomanry (dated April 1st, 1908): Surgeon-Major Arthur Brumell, Surgeon-Lieutenant Hamilton Drummond. Yorkshire Dragoons (Queen's Own): Surgeon-Major Percy Bernard

A. G. Mosbery, second prize (£1) and certificate. Senior: J. T. Duncan, first prize (£2) and medal; P. I. Wigoder, second prize (£1) and certificate. Practical Anatomy, first year: V. J. White, first prize (£2) and medal; I. M. Swanepoel, second prize (£1) and certificate. Second year: T. M. Thomson, first prize (£2) and medal; F. W. Warren, second prize (£1) and certificate. Practice of Medicine: R. Adams, first prize (£2) and medal; J. Menton and Miss C. F. Williamson (equal), second prize (£1) and certificate. Surgery: R. Adams, first prize (£2) and medal; G. C. Sneyd, second prize (£1) and certificate. Midwifery: J. Menton, first prize (£2) and medal; Miss I. M. Clarke and Miss C. F. Williamson (equal), second prize (£1) and certificate. Physiology: J. T. Duncan, first prize (£2) and medal; F. W. Warren, second prize (£1) and certificate. Chemistry: T. P. Roberts, first prize (£2) and medal; M. J. Hillery, second prize (£1) and certificate. Pathology: J. S. Pegum, first prize (£2) and medal; H. R. Tighe, second prize (£1) and certificate. Physics: M. J. Hillery, first prize (£2) and medal; T. D. Condell, second prize (£1) and certificate. Practical histology: J. T. Duncan, first prize (£2) and medal; L. W. Roberts, second prize (£1) and certificate. Practical chemistry: B. Kelly, first prize (£2) and medal; W. N. Harrison, second prize (£1) and certificate. Public health and forensic medicine: F. W. Warren, first prize (£2) and medal; H. R. Tighe, second prize (£1) and certificate. Materia medica: J. S. Pegum, first prize (£2) and medal; Miss N. Williams, second prize (£1) and certificate. Biology: M. J. Hillery, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Vital Statistics of Scotland.

A SUPPLEMENT to the annual report of the Local Government Board for Scotland containing statistics of notifications of infectious disease and of mortality has been issued as a bluebook. The number of cases of infectious disease notified under the Infectious Disease (Notification) Act, 1889, was 26,328 and of these cases 15,997 were treated in hospital by the local authorities. These figures relate only to diseases in respect of which notification is compulsory under the Act and they do not include diseases to which the Act has been voluntarily extended by the local authorities. Statistics with regard to the birth-rate and death-rate are also given. In 1907 the birth-rate in the landward parts of Scotland was 26·2 and in the burghal 27·5 per 1000 of their respective estimated populations. The death-rate in the landward districts was 14·4 and in the burghal 16·6 per 1000 of their respective estimated populations. The death-rate of infants under one year old was 91·0 in the landward parts and 117·9 per 1000 born in the burghal.

The Children Bill.

The Children Bill has received a third reading in the House of Commons and is now before the House of Lords. The modification of the clauses directed against juvenile smoking is considered likely to smoothen its further progress.

White Phosphorus Matches Prohibition Bill.

The House of Commons assented to the second reading of the White Phosphorus Matches Prohibition Bill without discussion on Oct. 19th. Its object is to prohibit the manufacture, sale, and importation of matches made with white phosphorus with a view to the protection from necrosis of persons employed in the manufacture of matches.

Tuberculosis Prevention (Ireland) Bill.

A Standing Committee of the House of Commons began consideration of the Tuberculosis Prevention (Ireland) Bill on Wednesday, Oct. 21st. The progress was slow and only a couple of amendments to Clause I. were discussed before the committee rose. No alteration was made in the text of the clause as a result of the day's deliberations. Clause I. imposes a duty on medical practitioners of notifying cases of tuberculosis to the medical officer of health in a district. This notification is to be made under regulation of the Local Government Board. Mr. T. W. RUSSELL, on behalf of the Irish Office, made an important statement on the principles which would guide the Board in issuing the regulations. He stated that the principal object of the Board would be to make it compulsory to notify such cases only as could be helped. Only cases of open tuberculosis of the lung would at first be notified and then only when the patients were living under conditions dangerous to other people. The Local Government Board would have no objections to consult a committee of medical men in regard to this matter. Some opposition was raised to the compulsory character of the notification clause during the discussions. The committee intended to resume consideration of the Bill next week.

HOUSE OF LORDS.

TUESDAY, OCT. 20TH.

Nurses' Registration Bill.

On the motion of Lord AMPTHILL the Nurses' Registration Bill was re-committed.

On Clause 2 Viscount WOLVERHAMPTON moved an amendment to provide that the name of the new body charged with the registration of nurses should be "The General Council for the Registration of Nurses in the United Kingdom."

The amendment was agreed to.

Clause 4 deals with the constitution and appointment of the Council.

Lord AMPTHILL moved an amendment to raise the number of members from 15 to 16. He explained that he did this for the purpose of adding a representative nurse from Ireland. The intention was also to bring Ireland immediately within the scope of the Bill instead of delaying its inclusion.

Lord ASHBOURNE commented on the desirability of giving more than one representative nurse each to Scotland and Ireland.

Viscount WOLVERHAMPTON replied that the number of the Council should be kept low in the interests of efficiency.

The amendment was agreed to, as well as a consequential one giving a seat on the Council to a nurse to be "elected by the nurses registered in the General Register whose registered address is in Ireland."

One of the subsections of Clause 4 provides for the presence on the Council of "three [illegible] edical practitioners to be appointed by [illegible] one to be a physician, one a surgeon, [illegible] of Lord ASHBOURNE it was amended so as to read as follows:—

"Three registered medical practitioners to be appointed by the British Medical Association [illegible] one to be [illegible] many of a drafting nature, were introduced into the other clauses.

Clause 23 imposed a delay on the application of the measure to Ireland until such time as it should be extended by an Order in Council, but [illegible] members of a family, and also it shall not apply to any person attending the sick for hire, who does not in any way assume to be a registered nurse under this Act." He stated that he did not personally think that the clause was [illegible] sing of the sick was in no way affected by th[illegible] number of the people concerned, particularly [illegible] profession, were anxious to see an actual safeg[illegible]

The Earl of MAYO suggested that a clause might be framed in the following terms:—"This Act shall not apply to or affect the nursing of [illegible] nder this Act, who does not in [illegible]" [illegible] ink the clause was necessary, [illegible] consideration. [illegible] ords of the proposed [illegible] the Bill they would [illegible] it did not contain. [illegible] on would like to see [illegible] make it abundantly plain that nurses who were not certificated nurses should be absolutely free to follow their calling.

The proposed clause was rejected without a division.

Lord AMPTHILL said that another clause stood on the notice paper in his name, but he did not press it as he did not think it was necessary, nor would it really add anything to the Bill. It ran thus: "Nothing contained in this Act shall be considered as conferring any authority to practise medicine or to undertake the treatment or cure of disease."

This proposal was not pressed.

The Bill passed through Committee.

HOUSE OF COMMONS.

WEDNESDAY, OCT. 14TH.

The Dairies, Cowsheds, and Milkshops (Ireland) Order.

Mr. Lo[illegible] applies equally to all persons engaged in the public supply of milk. Its object is to prevent the spread of disease by means of the milk-supply, and therefore it deals only with persons engaged in such supply as [illegible] which the Order was made. I am aware [illegible] er has been shown, but its provisions are [illegible] public health and it is not intended to withdraw it.

The Application of the Nurses' Registration Bill to Ireland.

Mr. LONSDALE asked the Chief Secretary to the Lord Lieutenant of Ireland whether he had received representations that the proposal to postpone the application to Ireland of the provisions of the Nurses' Registration Bill would inflict injury upon Irish nurses and training institutions in Ireland; and whether, in view of these considerations, he would move the Irish Local Government Board to make an effort to surmount the administrative obstacles which had led them to oppose the application of this measure to I[illegible]

The Government has placed on the [illegible] the immediate application to Ireland o[illegible]

The Suppression of the Use of Opium in China.

Mr. REES asked the Secretary of State for Foreign Affairs whether the edict of the Chinese Government banning the introduction into, and manufacture and sale within, the empire of morphine and hypodermic such an authority as Sir Harry Johnston I need add no more.

I am, Sir, your most obedient and humble servant,
ALFRED R. TUCKER,
Bishop of Uganda.
Bookham, Surrey, Oct. 13th, 1908.

To the Editor of THE LANCET.

SIR,—No one can deny the gravity of the problem which you discuss in your leading article in THE LANCET of Oct. 3rd under the above title. This matter is engaging the attention not only of the general body of missionaries in Uganda but also of those two able medical missionaries Drs. A. R. and J. H. Cook, who have for many years past sought by every means in their power to relieve the sufferings of the Baganda people and who have also found time to carry on scientific investigation. To them we have sent your article, and we have little doubt that they will desire to offer some comments upon the statements made therein. At the same time, as some weeks must elapse before we can hope to receive a reply from them, we have placed the article in question before the Bishop of Uganda, who possesses an almost unrivalled knowledge of the conditions of life in the Uganda Protectorate.

We will not venture ourselves to offer any opinion as to the causes of the serious increase of syphilis in Uganda of recent years, as we have not the advantage of first-hand knowledge of that region. We have, however, sufficient knowledge of the ravages of syphilis in other uncivilised lands to know that the causes of the rapid spread of the disease or its virulence under certain conditions are notoriously difficult to estimate.

We are, Sir, yours faithfully,
R. ELLIOTT, L.R.C.S. Irel.,
Secretary C.M.S. Medical Committee.
CHARLES F. HARFORD, M.D. Cantab.,
Physician, C.M.S.
Church Missionary Society, Salisbury-square, E.C.,
Oct. 13th, 1908.

DIVISION OF THE AUDITORY NERVE FOR PAINFUL TINNITUS.

To the Editor of THE LANCET.

SIR,—The account of the case in which I divided the auditory nerve was written at the end of last May and published in THE LANCET of Oct. 10th. Dr. Purves Stewart examined the patient on Oct. 18th last and he has kindly furnished me with the following supplementary account of her present condition :—

> She is poorly nourished, inclined to refuse food, and has mild delusions of suspicion. There is complete deafness of the right ear, as before, [illegible] yes on lateral deviation to either [illegible] is slightly weak, but the face, [illegible]. She stated to me that she still [illegible] ear, "like steam," not constant; she also added that before the operation this noise was constant and much more intense. She still, however, complains of intense discomfort in the right side of the head—a painful dragging sensation, which has not been influenced by the operation. She has a subjective salt taste all over the tongue and mouth, bilaterally. The sensory, motor, and reflex functions of the trunk and limbs are normal. I find no evidence of organic disease apart from the right-sided deafness and the paresis of the right pharynx. The loss of taste appears to have been due to implication of the Fallopian part of the facial nerve before you operated. The subjective gustatory sensation is doubtless functional in origin.

It is obvious that the case is one of much difficulty and that it is complicated, as many organic conditions are, by superadded functional phenomena. There is no doubt that the tinnitus which before the division of the auditory nerve was spoken of as culminating in pain is now practically gone; but there persists a distressing dragging sensation on the same side of the head which cannot easily be described and the cause and nature of which are entirely obscure.

I am, Sir, yours faithfully,
Oct. 19th, 1908. CHARLES A. BALLANCE.

To the Editor of THE LANCET.

SIR,—My friend Mr. Charles Ballance, in discussing his interesting case of division of the auditory nerve for painful tinnitus in THE LANCET of Oct. 10th, pp. 1070–73, refers to the well-known paper of Dr. J. Ramsay Hunt of New York on the Herpetic Inflammations of the Geniculate Ganglion (*Journal of Nervous and Mental Disease*, February, 1907). I write to mention that not only has Dr. Hunt recently written in the August, 1908, number of the *American Journal of the Medical Sciences* a further paper on the subject, but that in the August, 1908, number of the *Journal of Nervous and Mental Disease* Dr. T. J. Orbison writes on Herpes of the Membrana Tympani and attributes it to zosteroid affection of the petrosal ganglion. At present there is no post-mortem evidence as to the correctness of his view.

I am, Sir, yours faithfully,
Green-street, W., Oct. 13th, 1908. LEONARD J. KIDD.

THE CAUSE AND PREVENTION OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—The forcible letter by Dr. Harry Campbell in THE LANCET of Oct. 17th, p. 1176, on the prevention of dental disease is a welcome sign of the awakening interest on this important subject. While those who have made it a special study might suggest that prevention is not quite so simple, that hereditary influences have to be considered, that pre-natal conditions should be taken into account, and that feeding during the first few months of life is of vital importance, few will doubt that defective diet is the most important factor, and that with the medical profession lies the onerous task of teaching the lay mind that the organs of mastication must have suitable food and sufficient exercise if dental disease is to be prevented.

Not by way of criticism, still less through controversy, would I approach this subject, for your correspondent's closing lines disarm both. I would, however, venture very briefly to supplement his earnest appeal to the medical profession by endeavouring to explain how reform may be effected, and why it has not been done long ago. It is an indisputable fact that the medical practitioner's knowledge of disease enables him to guide the layman in matters of health, however simple the principles upon which such guidance is based. How can you expect the practitioner to prevent a disease when a knowledge of it is entirely absent? We are apt to imagine that dental disease and its disastrous effects are of quite recent origin; but there is very little evidence to prove that the national teeth are worse than they were 40 years ago; yet it would be impossible to find a disease—affecting 85 per cent. of the young adults in this country—which has been treated with such utter indifference by the medical profession.

I have dealt fully with this subject in the pages of THE LANCET[1] and there pointed out that on examining the final papers in London for ten years not a single question was found on dental caries. The remedy is quite simple and rests with the examiners—with the teachers, not with the taught; for so long as it is possible for the medical student to pass through his hospital training without being obliged to spend one week in the dental department, or answer a single question on the most prevalent of all diseases, so long will the prevention of dental caries be retarded and this national disgrace remain. I am, Sir, yours faithfully,

R. DENISON PEDLEY,
Dental Surgeon to the Evelina Hospital, Southwark.
Railway Approach, London Bridge, S.E., Oct. 19th, 1908.

To the Editor of THE LANCET.

SIR,—I have no desire to draw Dr. Harry Campbell into any controversy but I should like to point out how useless are such theories unless supported by facts. Can he produce any children who have been fed in the way described and who have perfect teeth? Against the diet theory there are many arguments. Teeth often decay as soon as cut and before the child has had much opportunity of doing them either good or harm. In out-of-the-way country places children are fed in just the same way as were their parents and grandparents and yet their teeth decay, while the parents often have sound ones. Every theory of dieting has been tried on the children of this generation without effect. I fail to see the use of laying down laws unless facts can be produced to refute these and many other arguments.

Of the three theories of the cause of dental caries—(1) diet,

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

HORROCKS, O., L.R.C.P. Edin., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Chatteris District of the county of Cambridge.

HOWARD, RUSSELL, M.S. Lond., F.R.C.S., has been appointed Assistant Surgeon to the London Hospital.

JONES, JOHN ELLINGTON, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Honorary Skiagraphist to the Bristol General Hospital.

OGG, T. A. W., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Rothes District of the county of Elgin.

PAINE, ALEXANDER, M.D., B.S. Lond., D.P.H., has been appointed Director of the Cancer Research and Pathological Department at the *Cancer Hospital*, Fulham-road, S.W.

ROBB, W., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Higham Ferrers District of the county of Northampton.

SUMNER, BENJAMIN, [illegible] been appointed [illegible]

TITTERTON, JOHN [illegible] Medical Officer [illegible] *Board of Guardians.*

WATT, P. C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and *Workshop Act for the* Gatehouse District of the county of Kirkcudbright.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—Junior House Surgeon. Salary at rate of £75 per annum, with board, residence, washing, &c.

BIRMINGHAM, PARISH OF.—District Medical Officer. Salary £350 per annum.

BLACKPOOL EDUCATION COMMITTEE.—School Medical Officer (female). Salary £200 per annum.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with apartments, board, and laundry.

BRISTOL EYE HOSPITAL.—House Surgeon. *Salary £70 per annum,* with board and residence.

BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary £60 per annum, with board, residence, &c.

BUXTON, DERBYSHIRE, DEVONSHIRE *HOSPITAL.*—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CAMBRIDGESHIRE, &C., LUNATIC ASYLUM, Fulbourn, near Cambridge.—Second Assistant *Medical Officer, unmarried.* Salary £120 per annum, with board, lodging, and attendance.

CANCER HOSPITAL, Fulham-road, London, S.W.—Assistant Pathologist. Salary £250 per annum. Also Medical Registrar. Salary £100 per annum.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—*House Surgeon.* Salary at rate of £50 per annum, with board and residence.

CHELSEA INFIRMARY, Cale-street, S.W.—Second Assistant Medical Officer. Salary £100 per annum, with board, washing, apartments, &c.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, washing, and residence.

COLCHESTER, BOROUGH OF.—Assistant Medical Officer of Health and School Medical Officer (female). Salary £200 per annum.

DERBY EDUCATION COMMITTEE.—School Medical Officer. Salary £250 per annum.

DREADNOUGHT HOSPITAL, Greenwich.—Assistant Physician. Also Dental Surgeon.

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary £120 per annum, with board and lodging.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House *Surgeon for* six months. Salary £25, with board, residence, and laundry. Also Assistant Physician. Also Second Medical Officer *for* six months. Salary at rate of £40 per annum, with luncheon and tea.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Physician for nine months. Salary at rate of £60 per annum, with board, residence, and washing.

FINSBURY DISPENSARY, Brewer-street, Goswell-road, *E.C.*—Resident Medical Officer. Salary £140 per annum, with residence, attendance, coals, and gas.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Physician.

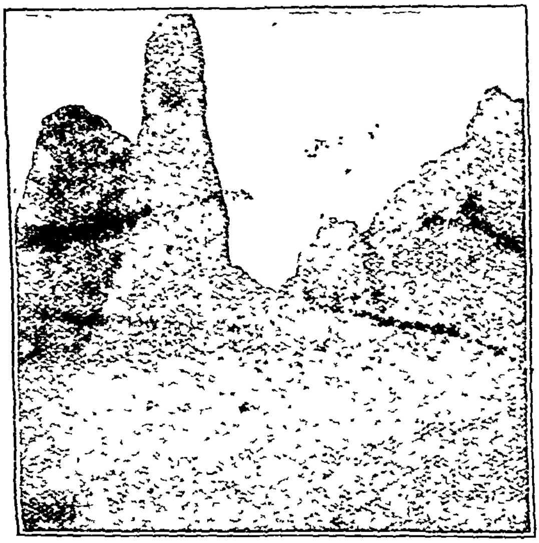
GLOUCESTER COUNTY ASYLUMS.—Junior Assistant Medical Officer. Salary £150 per annum, *rising to* £180, with board, lodging, and washing.

GUILDFORD, ROYAL SURREY *COUNTY* HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE, Virginia Water, Surrey.—Junior Assistant Medical Officer (female). Salary £150 per annum, rising to £200, with board, lodging, *laundry*, attendance, &c.

HOSPITAL FOR CONSUMPTION AND *DISEASES OF THE* CHEST, Brompton.—Resident House Physicians for six months. Salary £25. Also Assistant Resident Medical Officer. *Salary* £100 per annum, with board and residence an further north, and with several acacia and terebinth ees. The groups of fantastic rocks with the Nabatæan mbs lie mostly to the south-east. To the distant west es the gigantic table-rock of the Howweira; the sides are ecipitous, apparently of red sandstone, and the top would pear to be covered with black lava, much of which has owed over and formed blackish heaps at the foot. Still rther to the west is the craggy range of the Harra. The ectacle at Medaini-Salih is consequently a remarkable one. he heat here was considerable, the thermometer rising in e day to over 106° F.; but the air was extremely dry and strong wind blew the whole time, rendering this high emperature more or less supportable.

Fig. 8.



In the Mubrakat-el Naka gorge.

The improvised quarantine camp for pilgrims returning from the Hedjaz was put up at Medaini-Salih in each of the last two pilgrim seasons and traces of it can still be seen. It occupied a site to the east of the line and south of the *kala'at*. A ridge of sand (seen in the accompanying photograph, Fig. 9) along which the water-piping was laid still remains, running north and south, and dividing the area into two unequal parts. A series of ten primitive cordons was, it is said, established on either side of this ridge; those to the west were small and limited by the ridge and the railway; those to the east had unlimited space in an easterly direction. The only barrier round them was a cord stretched between posts, so that practically no true isolation of the different groups of pilgrims was possible. The "indigent," non-paying pilgrims were camped at the south end of the area, close to one of two so-called Nabatæan wells to be mentioned later. The camel-drivers (*akkams*) were similarly grouped round the other of these wells. The latrine arrangements in all these cordons were of the most primitive character, consisting of mere holes in the ground. The "hospital" was established in tents on the other (western) side of the line. The area just described is the best that can be found in this neighbourhood. It has, however, several disadvantages. After heavy rains it is in large part inundated, as, indeed, is the greater portion of the Medaini-Salih valley. This happened on more than one occasion last winter; the water stood, it is said, to the depth of half a metre and did not soak away for a couple of days. The caked, muddy surface of the desert still showed in many places where these inundations had occurred. The railway authorities have found this a serious difficulty for their buildings, and in order to cope with it are constructing all their new buildings at Medaini-Salih on artificially raised foundations, nearly a metre (in some cases more) above the general level of the plain. This involves, of course, a very considerable addition to the cost of construction, and in the event of houses having to be put up to quarantine 10,000 pilgrims the added outlay would be enormous. The site in question is also bounded on the south by the rocks above mentioned; these shut off the air and radiate a reflected heat from the sun which makes of this site one of the hottest we inspected. To the west of the line there is no suitable site, as the plain here, besides being very "accidentée," is also subject to inundation.

There is apparently an abundant supply of water at Medaini-Salih. The railway engineers believe that it occurs as a generalised underground layer of water through the whole valley, as wherever a well is sunk water is found: no movement has been observed in it, but as the land tends to fall slightly from north-west to south-east it is thought that the water, if it has any movement at all, may flow slowly in this direction. The soil is a soft sandstone (Nubian?) under a surface of alluvium; its permeability varies in different places and consequently the yield of different wells varies. The large station well close to the *kala'at* has the usual stone tower, with two large reservoirs, pump, and windmill close by it. It yields up to 125 tons of water in the 24 hours. A second well was being sunk at the time of our visit, just to the right (west) of the line, but it was not completed. Here the surface of the water was at 8 metres below that of the desert: there was only one metre of water, but it was intended to go to a depth of 3 metres. The reservoir by the *kala'at* contained stagnant water of a not very inviting appearance. Specimens of all three waters were analysed and gave the following results expressed in parts per 100,000. The well water (from the well with water-tower) was clear and had no smell; it contained 21·2 parts of chlorine as chlorides; the nitrogen was not estimated; the oxygen consumed in the permanganate process during three hours at 27° C. was 0·1983; the total hardness was 22·86 and the permanent 19·13. The total solids were not estimated. The other (unfinished) well water gave the following: colour slightly yellow; no smell; chlorines as chlorides, 17·5; total nitrogen, 0·2063, of which 0·0933 occurred as nitrates, 0·004 as free ammonia, and 0·009 as organic nitrogen; the oxygen consumed by the permanganate process during three hours at 27° C. was 0·2063; the total hardness was 25·12 and the permanent 13·31; the total solids were 76·7. Finally, the water from the reservoir (*burket*) by the fort gave the following analysis: the colour was yellowish; there was no smell; chlorine as chlorides, 29·7; total nitrogen, 0·342, of which 0·329 occurred as nitrates, 0·001 as free ammonia, and 0·012 as organic nitrogen; the oxygen consumed by the permanganate process during three hours at 27° C. was 0·2524; the total hardness was 27 and the permanent 22·52; the total solids were 154·6. Mention was made above of two so-called Nabatæan wells; they are situated towards the south end of the area occupied last winter by the improvised lazaret and not far from the rocks in which are the monuments. The more southerly one is about four metres in

Medaini Salih the site of last year's quarantine camp for pilgrims.

excite pity owing to weakness and loss of blood, and hence she was suffered to remain undisturbed with the images concealed under the camel's furniture.

We now come to the tragic close of her story. Jacob is journeying from Bethel when Rachel, who has again gone to full term, is taken in hard labour (chap. xxxv. 17 and 18), a significant statement twice repeated which points to the fact that there was great difficulty in the process. What more probable than that the fibroid growth had attained such a size as to impede the progress of the child? For no mention is made of a malpresentation as in another place (Gen. xxxviii. 28 and 29). The midwife who attended her was probably a stranger, her own nurse having died some time previously (chap. xxxv. 8) but had no doubt learned her previous history of disappointed hopes and encourages her to think that she will have "this son also." Finally the child is delivered alive, but worn out by the "hard" labour and weakened by previous hæmorrhages and ill-health the mother dies shortly afterwards. Whether her death was due to exhaustion or hæmorrhage and occurred at once or whether from septicæmia in a few days owing to sloughing of the tumour we cannot say, but in all probability her death took place soon after the birth of her child, for with her dying breath (chap. xxxv. 18) she names him "Son of my sorrow."

I am, Sir, yours faithfully,
O. B. TRUMPER, M.B. Vict., F.R.C.S. Edin.
Newtown, N. Wales, Oct. 13th, 1908.

THE DANGERS OF A LATE "LIGHTING-UP TIME."

To the Editor of THE LANCET.

SIR,—With reference to your valuable annotation, "The Dangers of a Late 'Lighting-up Time,'" in THE LANCET of Oct. 17th, p. 1161, may I bring to your notice that there is a very good rule for lighting-up time in the Locomotives Act of 1898, section 15, subsection 3, viz.: "The lights shall be carried between the hours of one hour after sunset and one hour before sunrise during the six months beginning the first day of April in any year, and between sunset and sunrise during the six months beginning the first day of October in any year." It is strange that this excellent rule was not adopted in the Motor Car Act of 1903, nor by the London County Council in their by-law respecting lights on vehicles, and it is also to be regretted that none of the above make any provision for lamps being lighted in fogs as is the rule in several foreign countries.

I am, Sir, yours faithfully,
Oct. 19th, 1908. A. G. WYNEN, Colonel late Dorset Regiment.

A WARNING.

To the Editor of THE LANCET.

SIR,—There is a man going about stating that he is my nephew with a card B. E. Osler, The Dale, Toronto, and Christchurch, Oxford. Will you please ask doctors to be careful. He has already bled several of my friends.

I am, Sir, yours faithfully,
Oct. 14th, 1908. WM. OSLER.

A BOTTLE CATALOGUE.

WE have noticed certain good features in the descriptions of medicinal bottles comprised in a catalogue illustrating bottles of all descriptions and sizes which we have received from Messrs. Kilner Brothers, Limited. The poison bottles, of which the lower part is fluted so as to be recognised by touch alone, whilst the upper part is plain, so as to afford space for the label, are of excellent design, and another innovation which will be welcome to many is the dispensing bottle with a screw stopper instead of a cork. The advantages of these are obvious, but we are not sure that they would be suitable for dispensing viscous medicines, as the rubber rings might not be readily cleaned afterwards.

◆

Thomas.—Our correspondent's question is rather too vaguely put to enable us to give a definite answer. Presumably sterilisation would occur were the towels left in for a sufficient time. As, however, it is probable that our correspondent means that the towels would only be left in the steriliser during the period of time for which the instruments are boiled—i.e., about 15 minutes—we do not think the sterilisation of the towels would occur, especially as probably they would be folded up.

Mr. T. Hanchard.—Upon examination of the article sent we hardly think that it presents the advantages which its inventor claims for it.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

of the Eyes. 2.30 P.M., Operations.

Obituary.

JAMES GREY GLOVER, M.D. EDIN., L.R.C.S. EDIN., L.S.A. LOND., J.P.

James Grey Glover was born in South Shields in 1832. His father, Alderman Terrot Glover, was a man of great ability and public spirit who played an important part in the life of his native town through a long and honourable life. His mother was a lady of exceptional strength and sweetness of character. James was one of the eight sons of these splendid parents and his early years were spent in that best of all schools of manners and character—a large and healthy family presided over by wise and godly parents. His whole course in life was an evidence of the strong influence of heredity and of the power of a robust and yet gentle and unselfish environment during the plastic days of youth.

He was sent to the best school in South Shields and was then apprenticed to Dr. Williamson, a surgeon in South Shields, who had a large practice and was a man of strong commonsense and sagacious judgment. The association of master and pupil was an altogether happy one and the close links of regard and affection formed in these early days never weakened with the flight of years and were only broken by Dr. Williamson's death a few years ago. Dr. Glover always spoke of Dr. Williamson with the highest regard, and to a younger generation the sight of the two men together showed how helpful the old and abandoned practice of medical apprenticeship was when master and pupil were loyal and wise. At the close of his apprenticeship he went to the University of Edinburgh, the great medical school of which was then at the very zenith of its fame. There he came under the powerful influence of such men as Christison, Goodsir, Alison, Syme, Gregory, and Simpson. He was a very keen student and the teaching and example of these men kindled his enthusiasm and stimulated all that was best in him. From the first he took a high place in his classes and at the close of his course carried off Dr. Alison's prize in practice of medicine. He graduated M.D. in 1854 and subsequently went to the Rotunda Hospital, Dublin, to obtain a thorough training in midwifery. Dr. Glover then went as assistant to practitioners in Wotton, in Leicester, and in Hounslow, and after this started in practice in his native South Shields. But his ambition was to go to London, and in 1858 he took a house there and furnished it, but the sudden death of his mother on the very day that he arrived in his new home altered all his plans and he returned to South Shields. However, in 1864 his old ambition asserted itself, and he returned to London and started in practice in Highbury, living first at 33, Compton-terrace, and later at 25, Highbury-place, a house which had once been the home of the Rt. Hon. Joseph Chamberlain.

It is well to recall what Dr. Glover was when he thus began his real life work and to note what special gifts and endowments he possessed. He was just 32 years of age, with a strong constitution, a keen intellect, an ardent nature, well disciplined in self-control, and intensely devoted to his profession which he regarded as a noble mission and for which he had trained himself by years of patient study and practical work. Added to these were a mind well versed in the best English literature, a distinct facility in speech and writing, a saving sense of humour, and above all a broad outlook upon life, a strong faith in the future, and a profound conviction that life was worth living. Fond of his fellow men, he had a keen eye for what was good in them and was inspired with a strong desire to remedy the social ills of the community as well as its physical ailments. And permeating his whole nature was a strong religious belief which widened his sympathies and gave him a courage and persistency which many of his associates envied. Such a man was not likely to confine his energies within any narrow channels or to use for self what was meant for a wider good. Soon after he settled in London he married Miss Muller, who survives him, in whom he found a worthy help-meet and whose gracious influence made his home a peculiarly happy one.

His first great interest was unquestionably in his practice. He was in many ways an example of the highest type of general practitioner; well trained as a student, thoroughly grounded in the science and art of his student days, he was keenly appreciative of the various advances of both the science and the art, and he was from the first an ardent disciple of Mr. Lister. Full of resource himself he was always ready to seek help and guidance in consultations but did not thereby relieve himself of responsibility. He had an admirable sense of proportion, took a wide view of a case, and was a wise adviser. In a rare degree he became the trusted and faithful friend of all his patients who held him in the highest esteem for his sterling uprightness of character, his helpfulness and unselfishness, and his singleness of mind in his regard for the interests of his patients. He rapidly secured a large practice and the hard work which this entailed was always relieved by the intense human interest and the many opportunities of doing good that it gave him. Admirable as a practitioner, Dr. Glover was eminently a publicist, taking a keen practical interest in all social and political movements. With considerable literary facility himself it was natural that he should seek for the expression of his views in the medical press. In 1862 he sent to THE LANCET an article entitled "*A Physiological View of the Premier*" (Lord Palmerston), which was accepted by the editor and published in the issue of June 14th of that year. It attracted unusual attention, was copied into nearly every paper in England, and was even referred to in some verses in *Punch*. From this date until 1902 he was a regular and most valuable member of our editorial staff. It may not be out of place to reproduce here some words which appeared in our columns on the occasion of his retirement:—"With unfeigned regret we have to announce that Dr. Glover has intimated to us his wish to retire from active work as a member of the editorial staff of THE LANCET. His connexion with our staff commenced in June, 1862, under the editorship of the late Dr. James Wakley, and has continued uninterruptedly to the present time. During this long period of more than 40 years we have invariably found him to be a true, trustworthy, and sagacious colleague and a personal friend of sterling worth. As, happily, he will read these words we must refrain from the full meed of praise that is his due; but he knows, we think, how highly his services have been appreciated by us and he has been so kind as to tell us that the appreciation has not been wholly on one side. ...... In the name of our predecessors in the editorial chair and for ourselves we thank him for the work which he has done and for the time which he has expended in the service of THE LANCET; perhaps we may go further and thank him for all that he has accomplished, or tried to accomplish, on behalf of the profession which he loves so well." Dr. Glover was particularly interested in all questions of professional ethics and in those matters in which the interests of the profession come into contact with the public life of the community. His judgment was sound, his opinions were expressed in clear, bright phraseology, and were inspired by that high ideal and generous instinct which characterised everything he did.

Reference may be made to three subjects to which he gave very special attention. He was one of the first and the most persistent of the advocates for the direct representation of the profession on the General Medical Council. Year after year he pursued in our columns this aim. He approached this question from the democratic standpoint, holding that the government of a profession, as of the nation, must be widely representative. With a varied experience of general practice in the provinces as well as in London, and at the same time intimately associated with medical consultants and teachers, he realised that a Council chosen from the latter did not, and could not, appreciate the peculiar needs and claims of the former. The discussion of this question was carried on by Dr. Glover with great persistence but without bitterness, and the success which he achieved was in no small part due to the broad, generous, and sympathetic spirit which had animated him throughout. When Direct Representation of the profession on the Council was granted it was generally recognised that Dr. Glover was marked out as a most suitable Direct Representative. He was elected by a large majority and was re-elected time after time, and it was not until after 16 years' service, when advised that it was necessary for him to lay aside some part of his work, that he announced his intention not to seek re-election. His election was by no means a reward for his splendid services in persistently advocating in these columns the claim of the profession to Direct Representation; it was far more than that. Dr.

JAMES GREY GLOVER, M.D. EDIN., J.P.

fitting position has been reached for speaking of the manner in which the application of carbohydrate to the purposes of life takes place.

For the proper comprehension of the nature of diabetes, it is necessary, as I have previously said, to have a right comprehension of the manner in which carbohydrate becomes physiologically disposed of within the system. Unless we stand upon sound ground here, we cannot rationally cope, in the practice of medicine, with the erroneous state existing in diabetes.

All are agreed that one destination of carbohydrate is in the production of fat. This, however, does not fall within the subject matter before us and therefore does not call for consideration to be here given to it. The point to be dealt with is the mechanism associated with the passage of carbohydrate from its seat of absorption in the walls of the alimentary canal to that of utilisation in the tissues.

Local absorption by the walls of the alimentary canal and utilisation in the tissues obviously imply that

THE CIRCULATORY SYSTEM HAS TO BE TRAVERSED.

In what way does this occur? The character of the respiratory quotient suffices to show that carbohydrate is used up as such in the tissues to which it must, therefore. of necessity be transported from the seat of absorption. It next follows that, in the mode of transport that takes place, there must be nothing to stand in conflict with the maintenance of what is observed, in respect to other conditions, to constitute the normal state. The point plainly put is,—Does the carbohydrate pass through the circulation in the form of free sugar, or does it, on absorption, become immediately placed in combination with other matter, and, in this locked-up state, become transported to the seat of utilisation? Let us examine the question that has been here put forward and see how the two propositions stand in the presence of the evidence that is respectively adducible in connexion with them.

First, let attention be given to the view that the carbohydrate of our food is conveyed in the form of free sugar through the circulation to the tissues. This view is comprised in the glycogenic doctrine, which also includes the production of sugar by the liver for furnishing a supply of sugar to the blood when the supply of carbohydrate from the food is in default. When the doctrine in question was first propounded, the liver was regarded, unlike the other organs of the body, as being loaded with sugar, and the blood issuing from it as containing sugar to a conspicuous extent larger in amount than was to be met with elsewhere. In addition to this, the blood contained in the systemic veins was represented as containing notably less sugar than was present in the blood of the arterial system—a fallacious assumption upon which was based a coincident destruction of sugar during the transit of the blood through the systemic capillaries.

All this is now put on one side, and even the French school no longer contends for that which was in former times confidingly accepted. Notwithstanding, however, that the experimental ground has so vastly changed, a lingering disposition exists to retain the idea that carbohydrate follows the course assumed under the glycogenic doctrine, and passes in the form of free sugar through the circulatory system from the seat of absorption to that of utilisation in the tissues, such passage of free sugar, either from the food or the liver, being regarded as a necessary condition of life.

Now the passage of sugar to the tissues means associated passage to the kidney, and this means proportionate outflow with the urine. In proportion as sugar is present in the blood so it may be confidently said is it present in the urine. Impermeability of the kidney to sugar used to be spoken of. It is a pure fiction, invented to escape from the difficulty arising from not finding sugar in the urine as an outcome of the imaginary flow of sugar into the circulation from the food and the liver. Up to a certain point, sugar, it was said, might be present in the circulation without showing itself in the urine, whilst when present beyond the particular point, an escape occurred and thus accounted for the state existing in diabetes.

Nothing could be more devoid of substantiality than such a proposition. However unwilling persons have been to admit that

NORMAL URINE CONTAINS SUGAR,

the fact of its presence must now, after upwards of 50 years of hard contention, be looked upon as fully established. The negative reaction given with Fehling's solution has constituted the source of the fallacious impression, but it has now been made clear that principles are present in the urine which have the effect of interfering to a certain extent with copper sub-oxide precipitation and thus concealing limited amounts of sugar. All this is now fully recognised, and sugar has been incontestably shown by other means to be present in normal urine.

The nature, indeed, of things is such that, in proportion as sugar is present in the blood, so it may be looked for to be present in the urine. Sugar belongs to the class of small molecular bodies, and we know that these, whether of a drug, saline, or other nature, flow off in association with the water of the urine from the blood circulating through the kidney. It is inconceivable that sugar could exist in the blood without passing off with the water of the urine; and experience shows, in cases of glycosuria, that the kidney is exceedingly sensitive to sugar, the urine being instantaneously influenced by any alteration of the amount of sugar in the blood.

In a paper on the effect of the intravenous injection of sugar on the urine, contained in Vol. XXIV., 1899, of the *Journal of Physiology*, I have given a number of prefatory observations on the condition of healthy urine in relation to sugar, and it is seen that much variation in the amount present exists. In some, the amount was considerably beyond that which, under preconceived notions, would be considered credible. Doubt, however, upon the point of validity, or about the figures being in the main part due to carbohydrate is removed by determinations having in each case been made before and after hydrolysis, and by the results that were thence obtained. With the other cupric oxide reducing principles in the urine, no increase of reducing power is by the hydrolysing process brought about, and therefore all the rise that took place, and in some instances it was considerable, must have been attributable to the presence of carbohydrate.

The amount of sugar ordinarily present in the blood stands at about 1 per 1000, and as the urinary water flows off, it is accompanied with a relative proportion of the sugar and other small molecular bodies present in the blood. According to the state of blood plasma, so, in this respect, may be expected to be the state of the urinary flow from it taking place through the tuft belonging to the Malpighian body. The larger

THE AMOUNT OF SUGAR IN THE BLOOD,

the larger will be the amount flowing off with the urine. With 4 grammes per kilogramme of dextrose intravenously injected, 47 per 1000 of sugar was found, in one of the experiments mentioned in the paper above referred to, in the urine collected within less than one and a half minutes from the commencement of the injection. The sugar literally runs off through the kidney like running through a filter.

There is good ground for inferring that the same line of action occurs with small quantities as with large, and that the urine coming, for instance, other circumstances being equal, from blood containing 1·5 per 1000 of sugar will contain proportionately more sugar than that coming from blood containing 1 per 1000. The fluctuation of sugar within certain limits in normal blood will thus account for the fluctuation that is observable in normal urine.

Activity of kidney will, of course, constitute an influencing factor. If the circumstances should be such as to lead to a low output of urine, the output of sugar will be low in proportion. If urinary water does not escape, there cannot be an outflow of sugar.

The percentage relation of sugar in the urine will also be influenced by the degree of concentration the output from the Malpighian tuft attains in transit through the uriniferous tubules. Hence degree of concentration, which is denoted by the specific gravity, constitutes an item that demands consideration. Indeed, through concentration, the sugar belonging to healthy urine may be relatively raised sufficiently to give rise to the production of a perceptible reduction with Fehling's solution, and it is known that medical practitioners have to be upon their guard not to interpret it in a wrong way and put it down as an indication of disease.

The point that I desire should be clearly understood is that the urine, alike for small quantities and for large, affords an indication of the state of the blood with reference to sugar, and that if, from any circumstance, there is an entry of free of argument. When I first knew him he was a practised and trusted writer. With him the style was the man. His writings were always lucid without glare, limpid but never shallow, sober but never dull, persuasive without softness, cogent without acerbity. Even when one differed from him in opinion it was impossible not to admire the sincerity of his convictions. Whatever he said and wrote was governed by a keen sense of responsibility, by a genuine desire to do and say what was *right*. Unselfish to the last degree he strove only for those things which he believed would enhance the honour and the usefulness of the medical profession and insure the health, happiness, and prosperity of the people. Briefly, Dr. Glover's life work was the outcome of a fine and cultivated intellect, a just, generous, and religious spirit. His memory will linger pleasantly in the hearts of all who knew him, while his loss will be long deplored by a large circle of patients and friends, and by none more acutely than the small and dwindling band of brothers who, a long generation ago, were associated with him in the honourable labour of medical journalism and medical politics."

Dr. W. Bruce of Dingwall writes: "The world is distinctly the poorer by the death of Dr. James Grey Glover of Highbury. Of how few of us after passing the allotted span of threescore and ten could that be said with truth. Not that there are not plenty of younger men, including his own talented son, to fill his place as a physician. But his was a shining light to his contemporaries, in so far as he was a remarkable example of a man whose sense of right and wrong was so plain and evident to all. Not for a moment did he ever waver when his conscience told him where his duty lay. To none are those lines of Horace more applicable—

> 'Si fractus illabatur orbis,
> Impavidum ferient ruinae.'

Dr. Glover possessed in an eminent degree the literary faculty not only of writing but in speaking his mother tongue with force and eloquence. To the end of his days he could quote largely and freely from the classic English authors. To those who were fortunate enough, like myself, to meet him when he could freely unbend, it was (and remains) a delight to have heard him declaim *ore rotundo* from Shakespeare, Milton, Pope, Byron, or other author some fine passage which his memory continued to retain as vividly as ever. As an old colleague of Dr. Glover on the General Medical Council I can truly testify, as doubtless will others of his fellow members, to his great interest in the work of the Council, as also to the respect with which his weighty words were listened to in that assembly. He worked very hard in the attempt, which unfortunately failed, to bring club doctors and club managers together on equal terms, yet the meetings of the Council's committee and the representatives of the great friendly societies parted, I am sure, with the greatest regard for each other. If it were allowable to withdraw the veil which properly is drawn over our friend's private life and his domestic surroundings, much might be said of the complete happiness of his home and of the high Christian conduct which guided his whole conduct and behaviour. With his sorrowing widow and family we must all feel deep sympathy for their irreparable loss of a loving husband and father."

Dr. J. P. Steele writes: "The Edinburgh school when Glover frequented its classes and graduated in its Senate-hall was at its best. In physics and chemistry, the professors were James D. Forbes and William Gregory; in anatomy, John Goodsir who, with philosophy and imagination, lifted the subject out of detail and made it intellectually, and even morally, fascinating; in physiology, Hughes Bennett; in surgery and obstetrics Syme and Simpson, the latter (as THE LANCET in its obituary notices of the two expressed it) the 'Napoleon, the former the Wellington' of their respective fields—the one brilliant in resource and initiative, the other minimising the chances of defeat; in materia medica, Christison; in pathology, Henderson; in practice of medicine, William Pulteney Alison, brother of the historian of Europe and uncle of the 'hero of Tel-el-Kebir.' It was the last-named professor who was Glover's favourite—not only for the breadth and depth of his teaching but for the high moral principle that, in address and in practice, glowed from him like a halo. Alison figures in Carlyle's 'Heroes and Hero-Worship' as the type of the philanthropic practitioner, as the 'Beloved Physician' not only in the gilded chambers of the rich but in the haunts 'where poor men lie,' as one who more than merited the eulogy of the Stoic satirist—

> 'Incoctum generoso pectus honesto'

(a nature imbued with a high-born sense of honour). All through life Glover was never tired of dwelling on the obligations under which Alison had laid him, and, to the best of his lights and his abilities, whether as a general practitioner, or as a medical journalist, or as a Member of Council, or as a citizen, he strove to do credit to the professional Gamaliel at whose feet he had sat. Long after Edinburgh had outlived her halcyon days, he maintained a warm side to her school—indeed, the only occasions when his kindly good nature would seem to have deserted him were those on which some critic, not always ill-inspired, ventured to contrast her present with her former self. But he would recover his equanimity in a moment, as he reflected that if Edinburgh, like Rome—

> 'Non è più com' era prima,'

(is no longer what she once was) she has but herself to thank, dethroned, as she is, like Saturn, by her own progeny who have from time to time been transferred to other schools, old and new."

The portrait represents Dr. Glover about 15 years ago.

JOHN TAYLOR, M.R.C.S. ENG., L.S.A.

THE death occurred at his residence at Ticehurst, Sussex, on Oct. 10th of Mr. John Taylor, at the age of 73 years. He first entered the army and served on the Army Medical Staff during the Crimean War and afterwards was surgeon on the s.s. *Calcutta*, having charge of military invalids during the Indian Mutiny. Returning home he settled at Emsworth, Hants, and took the diplomas of M.R.C.S. Eng. (1858) and L.S.A. (1859). In the year 1864 he removed to Ticehurst where he soon made a name for himself not only in the immediate district but over a wide area of East Sussex. It was not long before his practice became a large one, for John Taylor was highly esteemed by both rich and poor, on whom he spent equal skill and pains. In 1874 he contributed "A Successful Case of Colotomy" to THE LANCET, followed five years later, also in these columns, by an account of an operation for recto-vaginal fistula with imperforate anus in an infant. For many years he was one of the medical officers of the Ticehurst Union and also surgeon to the local Foresters' Court. It was at Ticehurst that he devoted the best years of his life until latterly his failing eyesight became such a source of anxiety to him that he was compelled to retire from the profession. It was a great blow to him to give up his work, but a greater yet was in store for him, for in 1902 his eyesight completely failed. During the last years of his life he was devotedly cared for by his wife and children.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. N. Gundobin, professor of children's diseases in the St. Petersburg Military Medical Academy, aged 48 years.—Dr. A. Tauber, formerly professor of operative medicine in the St. Petersburg Institute of Medicine for Women.—Dr. Friedrich Bezold, court councillor and professor of otology in the University of Munich, at the age of 66 years.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

IT is stated that the number of students, as contrasted with last year, has increased in every faculty and that in the medical faculty the entry is larger than in any of the past nine years except 1906, which was a record year. Certainly all the class-rooms and laboratories seem full of life and everyone has settled down to the routine of the winter's work. So far as the medical faculty is concerned there are few changes in the staff. Dr. R. A. Lyster has resigned his assistantship in the department of forensic medicine and toxicology, and Mr. George Heaton has resigned his position as assistant to the professors of surgery. Neither post has yet been filled, though it is probable that the council will fill the surgical vacancy in a short time.

The Opening of the Birmingham Sanatorium.

The sanatorium at Salterley Grange was opened last week result of its presence in the blood. As a matter of fact, observation shows that the water does not pass off and leave the sugar behind.

Plainly looking at the phenomena in these cases of alimentary glycosuria, what do we find? That no altered condition of the urine is induced by the ingestion of carbohydrate within a certain limit, but that when this limit is reached and surpassed, sugar shows itself in the urine in proportion to the extent to which the overstepping has taken place. If this applies to the urine, it must, upon the strength of what has been said, equally apply to the blood, and this brings us to the conclusion that up to a certain point, carbohydrate can be taken without adding to the amount of sugar present in the blood, whilst if taken beyond the specific point, the amount of sugar in the blood becomes augmented in like manner to that observable in the case of the urine.

Obviously, there must be a different issue connected with the carbohydrate which fails, as in the healthy state, to show itself, and that which, in consequence of a larger quantity being taken, shows itself in an abnormal manner to us. By those who retain belief in the teachings of the glycogenic doctrine, it is held that the carbohydrate of our food passes through the circulatory system in the form of free sugar to become oxidised in the tissues, and the abnormal presence of sugar is ascribed to accumulation from faulty oxidation.

This plainly expressed represents the view that is nowadays adopted in explanation of the source of diabetes by partisans of the glycogenic theory. If such a view were correct, oxidation, which varies with functional activity, would always have to be standing on a par with the carbohydrate food-supply, a very variable item, to escape from accumulation. There is variability in consumption of carbohydrate by oxidation, and much variability in the supply of carbohydrate from without with the food, and yet the two are to stand in such balanced regulation as to provide the constant immunity from accumulation that is required to account for the steady maintenance of the urine in the state that is observed. Looking, indeed, at the very small amount of ingested carbohydrate that is instrumental in altering the state of things in these cases of alimentary glycosuria, the constancy with which the precise point at which the alteration that occurs is maintained over a lengthened period of time, and the fact that the different rates at which oxidation of carbohydrate is carried on under different circumstances exert no influence on the result, I consider it is rendered

IMPERMISSIBLE TO SEEK IN THIS DIRECTION

for the explanation that is required.

Is it then possible, in view of the facts that are before us, for the carbohydrate of the food to pass through the circulation to the tissues in the form of free sugar without the transit being revealed by the agency of the urine? Upon non-carbohydrate food, the blood and urine are practically in about the same condition as upon carbohydrate-containing food, and the same, it may be said, applies to the fasting state. Although, then, the urine is such a sensitive indicator of the state of the blood with reference to sugar, and, although, if the food carbohydrate passed in the form of sugar through the circulation there should be a transit of sugar in proportion to the food carbohydrate taken, yet this is to occur without any sign of it being revealed by the urine.

Nothing short of the occurrence of an instantaneous disappearance of the sugar on reaching the circulatory system would meet what is wanted to escape from the output of sugar with the urine, and experiments on the intravenous injection of sugar suffice to show that this does not ensue. Even in experiments with the injection of 0·25 gramme of dextrose per kilogramme body weight, which amounts to only 1-4000th of the weight of the animal, the results show not only a given immediate *effect on the blood, but likewise that* the effect that is produced only tardily, it may be said, subsides. Coincidently, as might be expected, with the effect on the blood, there occurs an accompanying effect on the urine.

The circumstances connected with the passage of sugar into the circulation

BY MEANS OF INTRAVENOUS INJECTION

are not strictly comparable with those connected with its passage as a sequence to absorption from the alimentary canal. In the latter case, the influence that is capable of being exerted by the interposed liver has to be taken into account. In connexion with the glycosuric state, sugar derived from alimentary absorption passes into the circulation and thence into the urine, just as though it had been intravenously injected. There is, obviously, neither a stoppage at the seat of absorption nor in the liver. But what happens in the case of the carbohydrate falling within the certain limit that can be taken by the glycosuric without rendering itself manifest? Does this also pass into the circulation and become instantly lost by destruction in the tissues? The facts are diametrically opposed to the tenability of such a view, and if, under such circumstances, the carbohydrate passed as sugar into the circulation, it ought rationally to be expected to give indication of doing so, similarly to what occurs after direct introduction by intravenous injection.

Looking from all points of view at the matter that has been considered, the conclusion seems to me to be inevitable that the urine could not escape being affected by carbohydrate food, in proportion to the amount ingested, if transport took place in the form of free sugar through the circulation to the seat of utilisation in the tissues. And yet the view is still seen in some quarters to receive credence. For instance, an *à propos* illustrative case is to be found in the article on the "Metabolism of the Carbohydrates" contained in as late a publication as Leonard

HILL'S WORK ON "RECENT ADVANCES IN PHYSIOLOGY

and Bio-Chemistry," 1906. The article was written by Professor J. J. R. Macleod, now in Cleveland, U.S.A., but formerly a demonstrator of physiology at the London Hospital. Let us look into what is said, and give an eye to the groundwork on which the credence is based.

The article starts with notifying that carbohydrate matter constitutes the greater portion of our food and then specifying that it may range in standard daily dietaries, constructed for different amounts of muscular work, from 240 to 700 grammes. The consideration of how this carbohydrate becomes disposed of within the system is next entered into and dealt with upon lines falling within the teachings of the glycogenic doctrine. Notwithstanding the professed nature of the work in which this article is contained—of the work itself it may be said that, looked at as a whole, it has ably and usefully met a want that existed—it is found that in the article what can be unreservedly spoken of as obsolete errors are in an unqualified manner adopted and made use of as a groundwork for the conclusions set forth.

For instance, in antagonism with the showing of all modern work, it is assumed that the sugar normally present in the blood does not pass out with the urine and that it is only when it stands in excess of 2·0 per 1000, which is put down as constituting the maximum representation of the normal range for the sugar constituent of the blood, that it shows itself in the urine. "With a normal percentage (of sugar) in the blood, the kidney *allows none of the* sugar to pass into the urine, but whenever this percentage is exceeded, immediate leakage of the excess through the kidney filter occurs" (p. 313). Such is the physiology that is placed before advanced physiologists in connexion with this matter!

The first part of the statement is demonstrably untrue, and the second part is pure fiction. What is there to determine that below 2 per 1000, there shall be no escape, and above, an escape of sugar? The whole thing is not only contrary to fact, but opposed to common-sense reasoning. In reality, with 2 per 1000 of sugar in the blood, an outflow may be looked for sufficient *to produce* marked glycosuria. The results from intravenous injection justify this conclusion. And these premises, which formed a part of the groundwork upon *which the glycogenic doctrine* was based, are, in spite of the advance of knowledge that has taken place, put forward in the article in question *as if they* rested upon a substantial foundation. Evidence in every direction, in reality, unequivocally shows that sugar in the urine *runs* concordant with that present in the blood.

The author of the article afterwards, in speaking of the

FATE OF THE GLYCOGEN STORED IN THE LIVER,

says (p. 334) "there are two *so-called theories*, the one by Bernard, the other by Pavy," and then proceeds to pass judgment upon them, by framing four aphoristic propositions, based on Bernard's conclusions, and opposing to them statements that he puts forward as representing conclusions drawn by me. His deduction, which is emphasised

The Prevention of Malaria in Mauritius: Report of Professor Ronald Ross, C.B., F.R.S.

Professor Ronald Ross of the University of Liverpool, in his report on the prevention of malaria in Mauritius, recommends a vigorous campaign which will cost about £9000 a year. The destruction of many of the breeding-places of the malaria-carrying mosquitoes and the free distribution of quinine amongst infected persons form part of the scheme.

West Derby Guardians and the Accommodation for Aged Poor.

Mr. J. Lowry, Local Government Board inspector, was present at the last meeting of the guardians of the West Derby union and made remarks with reference to the proposal to build an institution on land at Alder Hey, West Derby, for the accommodation of chronic cases of bedridden old men and women. He said that the classification scheme, which was the great boast of the guardians some years ago, had to some extent broken down owing to the large increase which had taken place in the number of cases of old and enfeebled people. On an average there were at least 160 new cases in one or another of their establishments in the course of each year, and it was obvious that, as the population of the union grew and was growing, it was not likely that anything the guardians could do was going to reduce that increase. In these circumstances he regretfully came to the conclusion that further accommodation was necessary for this class of cases.

Annual Medical Church Service.

St. Luke's Church, Liverpool, was well filled on Oct. 18th (St. Luke's Day) on the occasion of the annual service specially arranged for the members of the medical profession. Amongst the officiating clergy were the Bishop of the diocese, the Archdeacon of Liverpool, and the Rev. J. B. Lancelot, Principal of the Liverpool College. The Very Rev. W. Page Roberts, Dean of Salisbury, was the preacher. The members of the medical profession occupied the nave of the church. The Lord Mayor (Dr. Richard Caton) and the Lady Mayoress were present. The offertory taken at the close of the service will be devoted, as in former years, to the British Medical Benevolent Fund. I understand that the net proceeds, after deduction of incidental expenses, will realise over £20.

Oct. 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh and Leith Medical Practitioners' Association.

THIS association, the origin of which was referred to in THE LANCET last week, held what may be regarded as its inaugural dinner on Oct. 16th. The chair was occupied by Dr. W. Nicol Elder, the President of the association, and about 130 members and friends sat down to dinner. The toast of "The New Association" was proposed by Dr. Norman Walker and responded to by the chairman. The proceedings were enlivened by songs and stories. It is thought that the association may be a means of social intercourse, while at the same time it will be prepared to take action in connexion with club practice and public appointments of different kinds.

The Lord Rectorship of the University of Edinburgh.

The term of office of the Right Hon. R. B. Haldane as Lord Rector of the University of Edinburgh having nearly expired, the students are busy with the candidature of their candidates for the office. The Unionists are running the Right Hon. G. Wyndham, the Liberals the Right Hon. Winston Churchill, while a third and non-political candidate is being run in the person of Professor W. Osler of Oxford. The election is usually political unless the two parties combine to support some man of outstanding repute in literature or in science. Professor Osler has many warm supporters, especially in the Faculty of Medicine, but if political feeling runs high, as it promises to do, the forecast is in favour of one or other of the political candidates.

Extension of the Glasgow Medical School.

As a result of certain communications relating to medical teaching at the Royal Infirmary, Glasgow, and addressed to the University Court, a committee was appointed last March to consider what steps should be taken to bring about a more equal distribution of students between the Western and Royal Infirmaries. At a meeting of the University Court recently the committee presented its report. In making certain suggestions it has not overlooked the fact that, owing to the proximity of the Western Infirmary and the special facilities which it affords for university instruction, the majority of the men students will continue to resort to it for their clinical work. The Royal Infirmary will always be at some disadvantage on account of its distance from the University. But the committee thinks that in view of the expansion of the medical school which may reasonably be expected to follow upon better organisation and an extended field, it appears desirable that this disadvantage should not be increased by the lack of a definite and mutually beneficial connexion between the two. The managers of the Royal Infirmary and the important bodies which are coöperating with them in this matter propose not only to provide the University with endowments amounting to about £1800 a year, which will suffice for the establishment of chairs in the subjects taken by students in the final stages of their course, but also to provide facilities, satisfactory to the University, for instruction which shall be open on equal terms to women and to men. In other words, they propose to enter into an arrangement with the University which is substantially the same as that now subsisting between the latter and the managers of the Western Infirmary. The following are the proposals submitted by the committee to the University Court:—

1. That the professorship of clinical medicine, and at the next vacancy the professorship of clinical surgery, be transferred from the Western Infirmary to the Royal Infirmary.
2. That in consideration of the stipend of each of these chairs being increased to (say) £500 a year, by means of funds procured by the Royal Infirmary, St. Mungo's College, and others cooperating with them, the professors be in future required to give systematic as well as clinical instruction at the Royal Infirmary.
3. That the election to the chairs be made by a board of curators, including representatives of the Court and of the Royal Infirmary.
4. That a committee of selection be appointed at the Royal Infirmary and a similar committee at the Western Infirmary, each including representatives of the University Court, which shall be empowered to nominate any of the respective physicians and surgeons in charge of clinical wards for appointment by the Court as University lecturers in clinical medicine or clinical surgery.
5. That the same committees of selection be empowered on the occasion of future vacancies to propose for election by the managers of each institution suitable persons to be appointed to the office of full physician or full surgeon in charge of clinical wards.
6. That in addition to the examiners who are professors *ex officio*, the lecturers in clinical medicine and clinical surgery be eligible in rotation for appointment by the court as lecturer-examiners for the final examinations.
7. That the fees paid by matriculated students for systematic courses conducted by the professors be paid into the general fee fund as at present; and that the fees paid for clinical courses conducted by the professors and lecturers be paid into a clinical fee fund, from which the stipends and class expenses of the lecturers (for teaching and examining) may be paid.
8. That the number of students attending a qualifying class for clinical instruction shall not exceed a limit to be fixed by the University Court.
9. That the managers of the Royal Infirmary, with the coöperation of the Muirhead trustees and others, provide funds for the endowment in the University of two new chairs, one for the teaching of pathological anatomy, the other for the teaching of obstetrics and gynæcology, to students attending the Royal Infirmary; and further undertake to provide facilities satisfactory to the University for teaching and examination in medicine and surgery and in the subjects of the new chairs.
10. That the election to the new chairs be made by a board of curators similar to that mentioned in No. 3 above.
11. That qualifying courses of instruction given at the Royal Infirmary by professors or university lecturers be open to all matriculated students on the same terms without distinction of sex, provided that the University may, for special reasons and with the concurrence of the managers, prescribe that particular courses or parts of courses shall be given to men and to women separately.
12. That the foregoing provisions as to fees and classes for clinical instruction do not apply to any existing professor until he shall have signified his assent thereto.

If such a scheme as the above be approved by the University Court before it can be carried into effect one or more provisional orders and certain new ordinances will be necessary. In the meantime it is probable that the court will postpone the election of a professor to the vacant chair of clinical medicine until it has arrived at a decision as regards the scheme which has been put forward by the committee.

Clinical Instruction in Obstetrics in Glasgow.

By the enterprise of the directors of the Maternity Hospital, under the guidance of the medical staff, it will now be possible to take full advantage of the clinical material available for the teaching of obstetrics in Glasgow. From the statistics of the hospital in the past it is evident that a great the seat of absorption in the intestine, during the height of absorption activity, following a copious ingestion of carbohydrate food) the writer in question gives data to show that only a comparatively small portion of absorbed sugar can be accounted for by conversion into liver glycogen, and that therefore, under the view advocated, there must be a large amount of sugar passing into the circulation at the time absorption is going on—a proposition opposed to the fact that neither the blood nor the urine affords evidence of such entry, although both are eminently sensitive to the entry of minimum quantities of sugar effected by the medium of intravenous injection.

The contrast is very great between the effect of the intravenous injection of sugar and that which follows the ingestion of sugar. In the one case, as I have just stated, the blood and urine are influenced in an exceedingly sensitive manner. In the other, as is well known, large quantities of sugar may be ingested without producing any visible effect. If passage into the circulation succeeded absorption, how could it come about that evidence of it could escape being discernible? Here lies the great error under which physiologists have hitherto laboured—the error of assuming that absorbed sugar can reach the circulation without being subsequently open to recognition.

Too much stress must not be laid upon the part played by the liver. I look upon it as simply supplementing the action occurring at the seat of absorption, and that, with a moderate amount of carbohydrate food taken, it is possible that little or no work may be thrown upon the organ. The position assigned to it, however, under the glycogenic doctrine is a far more material one, looked at from the side of the urine being kept free from sugar, inasmuch as it is supposed to constitute the sole agency by which the sugar from the food at the time of active absorption is prevented reaching the circulation in sufficient quantity to affect the urine. If it were not for this, it is considered, a temporary glycosuria would be consequent on a meal. How does this stand in view of the demonstrable fact that in different ways, (Eck's fistula, &c.)

THE LIVER MAY BE CUT OUT OF THE CIRCUIT

of blood without leading to the production of glycosuria? If there were nothing besides the liver to bar the direct passage of absorbed sugar into the general circulation, it is impossible to conceive, after the operative procedure referred to, that the urine could any more escape becoming charged with sugar after ingestion of carbohydrate food than it does after the intravenous injection of sugar. I do not propose to proceed any further with this matter at present, but shall have occasion to refer to it again later.

As the issue of what has preceded, it seems to me impossible that the absorbed sugar from carbohydrate food could possibly reach the general circulation in the form of free sugar without revealing itself by passing into the urine, just as it does in diabetes. During fasting, there is a given amount of sugar in the blood which is revealed by a correlated presence of sugar in the urine. Add to the sugar in the blood, and is the urine to escape giving evidence of the addition? If it did the circumstances would amount to the smaller quantity revealing itself and the larger quantity failing to comport itself upon similar lines. For sugar to reach the circulation without influencing the urine, there must be an immediate disappearance on entrance into the blood, and this, it is known, does not occur.

I have spoken of the facts which lead up to the conclusion that if the carbohydrate of our food reached the circulation for transmission to the tissues in the form of free sugar, it could not fail to give rise, proportionately to the amount doing so, to the presence of sugar in the urine, and thus the condition existing in diabetes. Let us now see upon what ground we stand, in relation to the matter, on applying the transport of free sugar hypothesis as a basis to work upon in the treatment of diabetes.

Looked at in relation to physiology, the glycogenic doctrine is the source of no embarrassment. The dictum is pronounced and nothing further follows, seeing that it is in no way subjected to

THE TEST OF PRACTICAL APPLICATION.

In the case of medicine, it is far otherwise. Diabetes, which arises from a physiological defect connected with carbohydrate metabolism, falls to the province of the physician to deal with, and here the trial of the enunciated physiological hypothesis comes in. Physiologists can look on with complacency, inasmuch as they, in their position, remain untroubled by the effect of error. Whatever the conventional physiological view that may be held, Nature proceeds unobstructedly with her operations, and the issue remains unaffected. To the physician, on the other hand, whose work lies in endeavouring to restrain the ill-effects of the faulty physiological action, the rightness or wrongness of the hypothesis upon which he is basing his procedure, counts for everything.

Now, what does the glycogenic doctrine imply? It implies the entry of sugar into the circulation, and this implies the passage of sugar into the urine, and next follows, as a resulting corollary, the origin of glycosuria from carbohydrate food. How is such a doctrine compatible with the state in which the urine is normally found? It itself, if put into application, would lead to the production of the glycosuric state. It may be said there is always a certain amount of glycosuria existing, harmonising with the limited glycæmia (independent of the functioning connected with our carbohydrate food-supply) that is normally present, and if this latter were increased by the effect derivable from carbohydrate food-supply, a corresponding addition to the normal glycosuria ought to be observed. The output of sugar that occurs after carbohydrate food taken in the presence of alimentary diabetes, gives an indication of the rate and amount of sugar absorption actually occurring.

The glycogenic doctrine

FAILS IN SUPPLYING A RATIONAL BASIS

of action viewed in relation to the treatment of diabetes. Indeed, as has been before stated, it has contributed to leading persons off in the wrong direction and to giving rise to suggestions which, if put into practice, could not do otherwise, as experience shows, than produce a downright pernicious effect. Diabetes being the result of a faulty carbohydrate metabolism, the possession of a right comprehension of the mechanism of the normal metabolism, ought to throw a guiding light on the direction in which to apply our efforts for bringing a counteracting influence to bear on the disease.

It is in this way that knowledge is the source of power. It gives us command over phenomena by enabling us, through the instrumentality of designedly modified conditions, to bring about a desired result. For instance, as previously referred to, since the knowledge of the microbic nature of the zymotic diseases was obtained, we have been placed in a position to combat the group of diseases in question with a power altogether different from that which we possessed before. Applying the glycogenic doctrine as a working basis in the treatment of diabetes, a want of congruity confronts us. It is professed to be natural and necessary that sugar should be constantly reaching the circulation, and yet the act of doing so leads to elimination with the urine. In spite of the fact that the system is suffering disastrously from the effects of the presence of a redundance of sugar, there is nothing to suggest, under the tenets of the glycogenic doctrine, that the food-supply of carbohydrate should be cut off, although experience shows that this line of procedure constitutes absolutely the only means by which an improved state of things can be brought about.

By the glycogenic doctrine the

MIND OF THE MEDICAL PRACTITIONER HAS BEEN DIVERTED

from what experience shows to be the right course as regards the treatment of diabetes. There is another matter bearing on treatment which has given rise to an immense amount of confusion and misguidance. I refer to the delusion created by deceptive diabetic food. Persons are too apt to conclude that because an article is advertised and sold as a diabetic bread-stuff it is to be accepted as suitable for use as such. The amount of starchy matter or sugar present, constitutes in reality, the criterion. This can easily be determined by analysis, and analysis is often showing that the reputed diabetic food is but little, or even, it may be, no better than food of an ordinary nature. The opening that here exists for liability to error must be intelligible to all. Not only, on the one hand, is treatment thwarted, but on the other hand, the foundation is laid for erroneous conclusions, touching the disease and its treatment, to be framed.

This brings me to speak again of the work of Professor von Noorden. I notice in Dr. Boardman Reed's translation of evil in the city. He allowed the present case to stand over till Nov. 13th, affirming the conviction but leaving the question of sentence to future consideration.

The School of Surgery, Royal College of Surgeons in Ireland.

The winter session of the School of Surgery of the Royal College of Surgeons in Ireland was inaugurated on Oct. 15th by Mr. J. Lentaigne, the President of the institution, who distributed the prizes of the previous session. He took the opportunity of calling attention to the fact that owing to recent university legislation the surgical school of their College would be the only unendowed and unassisted one in Ireland, for Trinity College had always been a well-endowed institution; the "Cecilia-street school" is about to disappear and re-emerge as the medical school of the new Irish University; while large additional endowments would accrue to the provincial schools of the Colleges of Cork, Galway, and Belfast. The President pleaded that as their own College had expended large sums of its funded capital in the effort to maintain its school at a high standard it could confidently appeal to the Government for protection from what would be a great "injustice," the being left to compete with liberally endowed teaching bodies both in Dublin and in the provinces.

Suicide by Strychnine Poisoning.

A case of suicide by strychnine poisoning was the subject of an investigation by the coroner for Dublin last week. The deceased was a vanman and had been out of employment for a week; according to his son's evidence he had "got a fall off a van ten years ago or more and his head was split. He was never the same after that when he would take a drink." He had purchased 20 grains of strychnine at the shop of a pharmaceutical chemist who knew him and to whom he represented that the poison was for a dog which was shut up mad at home and could not, accordingly, be brought out. He came home under the influence of drink, had some dinner, and then went to his bedroom and lay down. His daughter heard heavy moaning and found him "working as if in great pain." He told her and her brother that he had taken poison and they had him removed to Jervis-street Hospital, where he died shortly after admission. On procuring the strychnine at the druggist's he had signed his name in the usual poison register, thereby complying with the law. A copy of the Act of Parliament was produced by the druggist at the inquest. The coroner stated that he thought it "a very serious state of affairs that there is nothing to prevent any man getting poison and destroying himself or anybody else according to that Act." Medical men will probably agree in general with the opinion that further legal restraints are desirable in the sale of poisons—without even a physician's prescription.

Enteric Fever at Clontarf.

The epidemic of enteric fever still continues to hold its sway in Clontarf and has naturally given rise to general public interest in Dublin and to vigorous comments and important queries in the daily press. The solicitor of the milkman whose dairy was popularly incriminated again wrote at considerable length to the Local Government Board requesting a thorough investigation in the form of a sworn inquiry. He suggested that attention should be directed to certain points which would tend to clear his client from blame and would lay it on the public authorities who undertook excavations near his dairy. Many contradictory views have been expressed as to the cause of the trouble, and I am inclined to attach considerable importance to the following paragraphs taken from a letter written on the subject by Mr. J. Picton Bradshaw, a Clontarf resident:—

> Sir Charles Dallymount informs us that the filling of the Slobland Park is composed of street sweepings, &c. The "&c." is certainly three-fourths of the whole, and, as was clearly proved by recent sworn evidence, consists of the contents of ashbins and other vile and filthy refuse from the tenement slums and other premises, together with tons of decaying vegetable matter removed from various parts of the city of such an offensive nature that it is absolutely necessary to bring it through the city in covered carts. It is dumped at Fairview, scattered by workmen, turned over again by rag-pickers, while the high winds so prevalent along the shore road carry the smell, dust, and no doubt the microbe, far and near. Further, very recently a long deep trench was cut for main drainage purposes alongside the wall through refuse dumped there some time ago. The trench was some hundreds of yards long and the condition of the soil spoke without comment.
>
> Most of the houses in which the disease is located are not the old but actually the most modern, up-to-date, and recently built residences, all of considerable size, the drains, &c., of which have very recently been passed by the corporation officials.
>
> There is no doubt the recent heavy rains, followed by the exceptional heat and succeeded by the dry strong winds, have bred and scattered disease, carried on papers, dust, and other refuse over the Slobland Park, assaulting the pedestrians, tram and other passengers through Clontarf, and when we contemplate the probable source of these unpleasant missiles, and that they may be impregnated with germs from some typhoid-stricken slum tenement, we are filled with wonder we have so long escaped.

A Remarkable Rescue from Drowning.

The public recognition of a truly heroic rescue from death by drowning was celebrated by the urban council in Wicklow on Oct. 11th, when the brothers, Messrs. Edward and John J. Kennedy, were presented with the vellum certificates of the Royal Humane Society for rescuing a post-office employee who had sunk in 15 feet of water in Wicklow harbour last July. The event is of medical interest, for the Silvester method of artificial respiration was applied to the rescued lad for over an hour with no signs of success, and the onlookers gave up the case as hopeless. The brothers' efforts were, however, supplemented by police constables, and they were ultimately rewarded by seeing their patient gradually restored to animation. The degree of exhaustion was so great that he was detained for several weeks in the Wicklow Hospital before recovery could be pronounced complete.

The Belfast Medical School.

Work began in the Belfast Medical School for the present winter session on Oct. 20th, when the opening address was given in the Royal Victoria Hospital by Professor W. St. C. Symmers. The lecture, which was most humorous and full of sound advice, advocated the importance of pathological study. Sir W. Whitla presided and at the conclusion of the address a hearty vote of thanks was awarded to Professor Symmers, on the motion of Sir John Byers.

Oct. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Twenty-first French Surgical Congress.

IN my letter last week I described a part of the proceedings at the opening session of the Surgical Congress. Professor Forgue at the conclusion of his address pronounced a panegyric upon the members who have died during the course of the year. Their names are all so well known that I need only mention them. Hoffa (Berlin), Reboul (Nîmes), Loison (Military Medicine), Harrison (Liverpool and London), Folet (Lille), Reverdin (Geneva), and Terrier, our great French surgeon. The discussion of papers followed. The first, which dealt with the Surgery of the Biliary Ducts, was opened by M. Delangenière (Le Mans) and M. Gosset (Paris), and 14 other speakers took part in the debate. In the gynæcological section one of the most interesting of the first day's papers dealt with the Treatment of Extra-uterine Pregnancy. This was communicated by M. Albertin who has operated 62 times for this condition, 30 times by laparotomy and 32 times by the vaginal route. In dealing with severe hæmorrhage into the peritoneum he considers that it is sometimes an advantage not to be in too great a hurry to do laparotomy during the condition of shock, which, he says, is induced by the rupture of the tubal pregnancy rather than by the bleeding. A waiting policy for two or three days may afford an opportunity of operating under exceptionally favourable conditions. The 30 laparotomies, all of which resulted in cures, were done for non-infective cases. The colpotomies, of which two ended fatally and 30 successfully, were only performed for septic hæmatoceles. M. Albertin would reserve this operation for cases with large masses of infective blood clot in the pelvis and in which hæmorrhage is not the urgent indication. A very interesting discussion followed in which M. Pozzi, whose opinion carries great weight, said that he could not agree with this counsel of delay in dealing with patients suffering from sudden and severe intraperitoneal hæmorrhage, for it might very likely cost them their lives. He urged that not a moment should be lost in performing laparotomy in a case of ruptured extra-uterine pregnancy. He had operated during the stage of shock upon patients who would certainly have portal vein can be ligatured and the liver extirpated, without interfering with the circulation through the other abdominal organs. In one recorded experiment, the liver was extirpated after the administration of 25 grammes of dextrose and 25 grammes of starch. During the succeeding 10 hours, 220 cubic centimetres of urine were collected, which, on subjection to alcoholic extraction, yielded an indication of the presence of 0·5 gramme of dextrose. A further 200 cubic centimetres were secreted during the night, and this was found to be free from sugar. In a second recorded experiment, 75 grammes of dextrose were employed. During 12 hours after the operation, 330 cubic centimetres of urine were obtained in which 4·2 grammes of dextrose are stated to have been found, which represent a minute portion only of the dextrose administered. The intestinal contents, it is mentioned, only contained a trace of sugar.

Eck's fistula is the name given to an operative junction of the portal vein with the inferior cava, permitting of the former vessel being tied above the junction and thus cutting off the flow through the liver without interfering with the circulation through the abdominal viscera. The operation is naturally a very delicate and risky one, but it has proved susceptible of being performed upon dogs with survival of the animals in a satisfactory condition for a considerable time afterwards.

Hahn, Massen, Nencki, and Pawlow have published a communication in Schmiedeberg's *Archives*,[2] containing the results of observations on the effects of the operation upon the system. The operative part of the undertaking was performed by Massen and Pawlow, and the chemical part by Hahn and Nencki. A striking effect noticed was the production of an intolerance of animal food. The dogs subsisted well upon bread and milk, but meat produced a toxæmic state accompanied with various manifestations of nerve disturbance. The authors state that they never found albumin, albumose or sugar in the urine, but there is no indication of any idea of looking for sugar in connexion with carbohydrate food administration as a sequence of the position in which the liver was placed.

A communication entitled "On Carbohydrate Metabolism in Dogs with Eck's Fistula, whereby the Portal Blood passes direct into the Vena Cava without traversing the Liver" has been recently published by F. De Filippi of Rome in the *Zeitschrift für Biologie*.[3] A series of observations was conducted upon the toleration of various carbohydrates after recovery from the operation, and finally the actual occlusion of the portal vein was verified by post-mortem examination. The ordinary food administered consisted of bread and milk and wheat-flour porridge, which never, it is stated, produced glycosuria. After the different sugars, however, glycosuria occurred when certain quantities were reached standing below those required to produce glycosuria in the case of dogs in the normal state.

Corresponding results, I perceive, are stated to have been obtained by other experimentalists. For instance, I observe it stated [4] in connexion with the fate of sugar given to dogs with Eck's fistula, that Popelski, in 1898, found, after feeding with large quantities of saccharose, that against 1 per cent. of the ingested sugar eliminated by normal dogs, 13·5 per cent. was eliminated by the dog with the fistula; and quite recently mention is made by P. B. Hawk [5] of absence of glycosuria having been observed in a dog with Eck's fistula on a diet of milk, bread, and potatoes. The concurrent testimony seems to be that whilst sugar can lead to the production of glycosuria, starchy matter, on the other hand, fails to do so.

Everything points to the existence of a missing link in the chain of events thus far reckoned to occur in connexion with the passage of carbohydrate from the seat of absorption in the walls of the alimentary canal to that of utilisation in the tissues. We know that small quantities of sugar reaching the circulation by intravenous injection, lead to the production of glycosuria, and why should they not do so when absorbed from the alimentary canal? The liver has been credited with safeguarding the circulation from the entry of sugar in a manner to occasion glycosuria, but how do things stand in the face of the evidence that has been just adduced, founded upon the state observed to exist after the abolition of the influence of the organ?

HEREDITY IN DISEASES OF THE NERVOUS SYSTEM.[1]

By Sir WILLIAM R. GOWERS, M.D. Lond., F.R.S.,
CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, LONDON, W.C.

THE scientific study of heredity, which has undergone so wonderful a development, especially since the mists were swept away which for long had hidden Mendel's work, cannot be applied fully to the diseases of man. The human race is not open to Mendel's essential methods, and its mere complexity of development involves innumerable differences from lower forms of life, the effects of which may be greater than we can well realise. Potential fallacies surround almost every inference that can be drawn. We can seldom look back far at preceding generations and the future we must leave to those who may follow us. The difficulties of precision and fulness of knowledge are great and the chance fertilisation, from which the flowers of Mendel were guarded by his paper bags, is the rule in the human race, unalterable by us, however we may wish. Hence it seems useless even to apply the hereditarian terminology to facts that are in general inconsistent with its grounds. I can only hope to present a few of the general facts of heredity in some diseases of the nervous system, well known as they are, and I trust that they will be supplemented by others. We are only in the stage of random observation.

Among diseases of the nervous system are commonly included many that are not of it but merely in it, and these can scarcely be included. Tumours of the brain and spinal cord are allied to morbid growths in general for the most part. Yet many of them have a special relation to nervous tissue, such as gliomata, composed of the special interstitial elements of the nerve centres. Endotheliomata, growing from the lining tissue of the cavities and surface of the brain and spinal cord, we do not know how to class, whether with the centres in which they are found or with growths of the same character elsewhere. But all such affections are so rare that they have not yet justified any suggestion of heredity. This is also true of another condition in which heredity might reasonably be expected, the defect in the coarser formation of the spinal cord which leads to the cavities and undeveloped embryonal tissue adjacent of syringomyelia. It is sometimes found after death when there have been no symptoms to suggest it. When the causal arrest of development has occurred earlier and involved the inclosing structures it constitutes a state often conspicuous in infancy, spina bifida. Heredity in these affections may be thought likely, but no ground for it has been, I think, discerned, and may not be until every member of the family can be scrutinised after death. Insular sclerosis is another affection in which heredity might be expected according to one view of its nature, but no facts have suggested it.

Sudden cerebral seizures, apoplexy and the like, depend upon causes that take their heredity far away from the brain in which the lesion occurs. Yet the frequency in which heredity is active is most notable. In some families many members suffer earlier in life than the malady is really common. But we must look to the vessels and the cause of their degeneration for the mechanism by which the disease is produced and through which heredity acts. Toxic states, various in nature and origin, chemical and microbial, are potent causes of disease, but the range of heredity in their occurrence is small. The so-called "inherited syphilis" has, of course, nothing to do with heredity. I do not know of any observations on the children of those who suffer from it and their life-histories. Any influence heredity may have on the liability to suffer from bacterial maladies affecting the nervous system may, perhaps, be suggested by the discussion on the similar facts regarding tubercle. The part it may play in the secondary production of chemical agents from organisms acting on somatic processes is an important problem. It is presented by the paralysis that sometimes follows diphtheria. The experience of our fever hospitals may furnish evidence for or against any family tendency to suffer disagreed from the first with the establishment of the academy, did not send their patients there. The result was that the expenses of the academy were much higher than had been anticipated, and at a recent meeting of the Düsseldorf town council some members even suggested the dissolution of the academy. Although this suggestion was not adopted the enthusiasm of the Düsseldorf municipal authorities and of the ratepayers has dropped considerably. The Government had expected that other towns also would favour the establishment of academies but this is very unlikely after the experiences of Düsseldorf. The municipal authorities of Frankfort, where an academy had been planned, abandoned the scheme some time ago chiefly on account of the unanimous protest of the medical profession of the city.

Oct. 20th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Deaths from Wild Beasts and Snakes.

IN a resolution issued at Simla by the Home Department it is stated that the total mortality amongst human beings reported to be due to wild animals in 1907 amounted to 1966 as compared with 2086 in 1906. The total is the lowest on record since the practice of the collection of these statistics was initiated. The most noticeable variations from the figures of last year occur in Bengal, the United Provinces, and the Central Provinces, while in Madras there was a comparatively large increase of from 167 to 201 in the number of persons killed by tigers. In Bengal the mortality rose from 756 in 1906 to 840. In the United Provinces the mortality fell from 280 in 1906 to 159. The decrease is principally due to a noticeable decline in the number of deaths caused by wolves in the Allahabad division. The mortality in the Central Provinces fell from 262 in 1906 to 174 in 1907. The total mortality amongst human beings caused by snake-bite fell from 22,811 in 1906 to 21,418 in 1907. So low a figure has not been reached since 1897. The decrease is noticeable mainly in Bengal and Eastern Bengal and Assam where the figures fell from 8862 and 2730 in 1906 to 8276 and 1900 respectively in 1907. The most important increases occurred in Madras and Burma, where the figures rose from 1527 and 1149 in 1906 to 1977 and 1348 respectively. The highest mortality in Bengal occurred as usual in the Patna division, the number of deaths being 3393 as compared with 3636 in 1906. The decrease in Eastern Bengal and Assam is attributed to the floods having been lower. The figure for the Central Provinces (995) is the lowest returned in any one of the last seven years. The Lauder Brunton treatment of snake-bite by incision and application of permanganate of potassium and the distribution of lancets continue. It is too early yet to pronounce with any certainty as to the result of the experiment but a number of favourable reports have been received. Eight cases are reported from the United Provinces of the successful use of Dr. Calmette's antivenene. In two of these cases the permanganate of potassium treatment was also employed. Colonel R. D. Murray, I.M.S., Inspector-General of Civil Hospitals of the United Provinces, gives illustrations as to the value of the anti-venomous serum and permanganate of potassium in the treatment of snake-bites. He complains, however, that all serum issued from this Central Research Institute, whether to the Government or local fund institutions or to private institutions or persons, is charged for at Rs.3 12 annas per tube, whereas formerly it was supplied free of charge to dispensaries maintained by local and municipal funds. The price fixed by the Government of India, he observes, makes the use of this valuable remedy almost prohibitive in dispensaries which are not favourably situated as regards funds. The United Provinces local government has advised the Inspector-General that if there are any dispensaries in localities where cases of snake-bite are frequent which stand in need of special assistance in this respect the Inspector-General should consider, in communication with the chairman of the district board, whether it would be advisable to increase the grant for European medicines.

Insanity and Asceticism.

In the interesting work of Major G. F. W. Ewen, I.M.S., on "Insanity in India" notice is taken of the connexion between some forms of insanity and the practices of ascetics. It is not only the effect upon the patient, however, which has to be considered in this connexion. One great obstacle to the work of neuropathic experts is the firmly rooted idea in the mind of the patient's friends that the affliction, according to the character of its manifestations, is either a subject for veneration or a punishment occasioned by mystic forces. Either the man has insulted a priest or defiled a temple, or he is a saint and greatly endowed in some way which gives him superiority to his fellows. One, Mahomed Bux, was so insane as to be almost incomprehensibly incoherent and so deficient in control that he once committed murder, yet he was regarded by the whole of Lahore, Mahomedan and Hindu alike, as a holy and powerful man who by much meditation had gained control of a "Jin" and could grant his applicants any favour. To him went rich merchants, graduates, and even native medical men who could discourse learnedly on the nature of this very disease but whose superstitions were still more powerful than their learning.

Sept. 30th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the quarterly meeting of the council of the above College on Oct. 15th the following diplomas were granted:—

Diploma of Member.—John Joseph Cameron, M.D. Toronto, Toronto University and London Hospital; and Charles Ogilvie Lillie, M.B., Ch.B. New Zealand, New Zealand University and Middlesex Hospital.

Licence in Dental Surgery.—Edgar Smith, Guy's Hospital; and Arthur Brookes Thomason, Victoria University, Manchester.

KING'S COLLEGE.—The council of King's College has made the following appointments: Dr. StClair Thomson as professor of laryngology in King's College Hospital Medical School, and Mr. H. Moore as assistant lecturer in physics.

UNIVERSITY OF CAMBRIDGE.—The Gedge prize has been awarded to E. Mellanby, B.A., Emmanuel College, for his essay on creatine and creatinine.—Dr. Liveing, late professor of chemistry, and the Master and Fellows of Caius College and of Sidney Sussex College, have presented valuable apparatus and chemicals to the University chemical laboratory.—The following degrees were conferred on Oct. 15th:—

M.D.—H. F. Horne, King's; and H. J. Fardon, Christ's.

The following have passed the Sanitary Science Examination:—

J. H. H. Baillie, Victoria E. M. Bennett, Catherine L. Boyd, Dora E. L. Bunting, J. S. Clark, J. C. Dunn, J. Glaister, C. A. Gourlay, A. H. Griffith, S. A. Tim. Henry, J. S. Higgins, W. C. Hossack, Elizabeth M. McVail, E. P. Minett, C. B. Moss-Blundell, K. K. Mukhopadhyay, A. Richmond, D. Stewart, J. L. Stewart, R. S. Turton, and Lilian E. Wilson.

—The Committee for the Study of Special Diseases is about to elect a qualified medical lady to the R. C. Brown scholarship in special pathology. The annual value of the scholarship is £150, in addition to laboratory expenses. The holder of the scholarship will be required to undertake clinical research in connexion with the bacteriology of certain chronic infections associated with rheumatoid arthritis. Application, giving an account of previous medical and laboratory experience, together with three references to former teachers, should be sent in not later than Oct. 28th. Candidates are requested not to send testimonials. For further particulars application should be made to Mr. T. S. P. Strangeways, Department of Medicine, Cambridge University.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore (College of Physicians and Surgeons)*: Dr. C. W. G. Rohrer has been appointed Assistant Professor of Medicine and Therapeutics.—*Graz*: Dr. Rudolf Polland has been recognised as *privat-docent* of Dermatology and Syphiligraphy.—*New Orleans (Tulane University)*: Dr. J. B. Guthrie has been promoted to be Assistant Professor of Medicine and Therapeutics.—*Philadelphia (Women's Medical College of Pennsylvania)*: Dr. H. C. Deaver has been appointed Professor of Surgery in succession to Dr. William L. Rodman, resigned.—*Vienna*: Dr. Josef Möller, Professor in the University of Graz, has been appointed to the chair traced seldom but sometimes remarkably. I think it is probable that we shall hereafter find that special forms of heredity are associated with other characters in a manner that will make it an aid in distinguishing maladies that are now classed together but for this we must wait.

A third class of diseases in which heredity is operative consists of the so-called functional affections. Some of them vary extremely in degree and baffle attempts to group them so as to discover their relation to heredity. Such are hysteria and the defective nerve strength which may manifest itself in varied ways and which we are all drawn, sometimes against our better judgment, to designate "neurasthenia." Other functional disorders, such as chorea and neuralgia, have relations too complex for the clear discernment of heredity; and migraine, defined as it is, is connected with quite different constitutional states than disease of the nervous system. Two forms of functional disease have been much studied in relation to heredity, epilepsy and insanity. I propose to confine myself to epilepsy, leaving the relations of insanity to those who take part in the subsequent discussion.

Some cases of epilepsy are outside our subject. Those that result solely from organic lesions of the brain, from disease, or trauma, or difficult birth are not concerned with heredity. I confess I have always acted on the belief that the tendency to convulsion in such acquired cases, without other evidence of disposition, may be regarded as not transmissible. I have never hesitated, on this ground, to permit the marriage of a sufferer, and I have not had any evidence to show that I was wrong in doing so, however early in life the damage arose. I do not question the guinea-pigs of Brown-Séquard, but I do question an inference from guinea-pigs to men. But such cases of "organic epilepsy" are rare. They constitute so small a proportion of the cases as to have little influence in statistics of heredity. The difficulties in ascertaining the facts of family histories are vast. Among hospital patients genuine ignorance often hinders. A woman brought her son for epilepsy and denied that any of his relations had had fits. As soon as she had gone out of the room she returned with two of his brothers suffering from them. It had not occurred to her that a brother is a relation. In patients seen in private the stigma supposed to attach to some diseases leads to concealment, which produces actual ignorance in another generation. A middle-aged lady, with an epileptic nephew, denied any neurotic antecedents and was indignant when I told her that three great-aunts had been in asylums. But it was so.

In my own inquiries into the heredity of epilepsy I have limited myself to these two maladies, epilepsy and insanity. I find that in the cases seen in private there is a family history of one or both in 47 per cent., in antecedents and present or past collaterals. The difficulties I have just mentioned justify the assumption that at least 50 per cent., and probably more, really present a family tendency. Among hospital patients the number is not more than 35 per cent., so great a difference does ignorance apparently make. In the facts presented the percentage was taken from 2400 cases, of which 600 were seen in private. Heredity was ascertained in 39 per cent. of 1193 males and 43 per cent. of 1207 females. These proportions are much less than have been ascertained by others who have included a larger number of diseases. It may be well to confine myself to the cases in which a parent suffered. Jeremy Taylor tells us in one of his sermons that "an epileptick son doth often come from an epileptick father." Of the total cases in which inheritance was paternal the father himself suffered in 40 per cent., when maternal the mother suffered in only 36 per cent. When epilepsy itself occurred in a parent it was the father who was epileptic in 49 per cent. of the cases, the mother in 51. The cases with insanity in a parent are only one-third the number with parental epilepsy. Of the cases with parental insanity, the father was insane in 37 per cent., the mother in 63. One effect of heredity is to increase the female cases. Where it was absent the excess of males amounted to 4 per cent., but in cases with heredity the same excess was presented by females. This is partly due to the fact that inheritance is more frequently from the mother's side by 13 per cent., and that then females are in excess by 18 per cent. The influence of heredity is sometimes strikingly emphasised by the number of sufferers in a family. In one instance six brothers suffered, their mother, two of her sisters, and both her parents. In another five sisters, five of their children, the mother, her brother's son, and her own mother.

Such facts might be multiplied almost indefinitely regarding many diseases. We are told we are working on an entirely wrong method. Diem states that he has found neuropathic heredity in nearly 70 per cent. of healthy persons. If he has included every conceivable malady that involves the nervous system it is quite credible but of no significance. It has been urged that the essential facts for every member of each generation must be recorded to make observations of value. We hope to learn much regarding method from those who are here to-day. They have devoted much time and much ability to the scientific study of heredity, and they may tell us how to make our own observations more effective.

Queen Anne street, W.

HEREDITY IN CANCER.[1]

BY E. F. BASHFORD, M.D. EDIN.,

GENERAL SUPERINTENDENT OF RESEARCH AND DIRECTOR OF THE LABORATORY OF THE IMPERIAL CANCER RESEARCH FUND.

THE successful application of the comparative and experimental methods appears to be greatly narrowing the field of inquiry and dismissing many explanations of cancer—previously held with good reason—from further serious consideration. Although this is the case, we still know very little as to its etiology beyond the fact that it manifests itself under the most divergent conditions and in such a way that we may have to entertain the possibility of several etiological factors, some of which are external and some internal to the body. To these factors we are only justified at present in assigning an indirect and mediate etiological significance. The most satisfactory explanation of the causation of cancer will probably be that implied by the accurate description of the nature of the transformation of normal into cancer cells when this advance in knowledge shall have been attained.

In surveying the incidence of cancer in the vertebrate kingdom one has been struck by the fact that certain forms of cancer appear to preponderate in different classes. It is, of course, obvious that the incidence of cancer in representatives of the different zoological classes must differ, since, e.g., structures peculiar to mammals are absent in other vertebrates. But if we consider the mammalia themselves, it appears probable that some species are very liable to forms of cancer, from which others even nearly allied are relatively or altogether exempt, as illustrated, e.g., by the variations in the frequency with which cancer of the uterus or mamma occurs. Cancer of the breast, so common in the human female, is also common in the mouse and dog, but practically unknown in the cow, which, however, suffers quite frequently from primary growths of the liver and adrenal. These tendencies are so constant that it is difficult to escape the conclusion that they depend on innate characters which are hereditarily transmissible, and there can be no doubt as to their etiological importance, although we cannot yet penetrate to their meaning.

Even in the same species we meet with similar idiosyncrasies—e.g., in the greater liability of grey than of other horses to melanotic sarcoma. It may, of course, be argued that these peculiarities in the incidence of the disease are determined by peculiar environment, or by the use to which the organs are put in different species, although this would hardly hold for grey as contrasted with other horses, the disease in question affecting only the pigment cells of the skin. If we compare the tame albino mouse with the wild grey mouse the incidence of cancer is parallel in them, although the two varieties live under very divergent conditions; therefore the liability of the mouse to carcinoma of the mamma appears to be due to an innate tendency.

When we compare the large natural groups of vertebrates, or even the species of the mammalia, the grounds on which we may assume that differences in the incidence of cancer are innate and hereditarily transmitted appear safe. But fits in heart-block in man (Adam-Stokes syndrome) and the relationship of the vagus to the fits. VII.: Methods of measuring the arterial pressure, the venous and the capillary pressures; the peripheral resistance, its seat and influence. VIII.: The filling of the heart, the influence of posture and muscular movement; back congestion; effect of plethora, hydræmia, and hæmorrhage.

---

[1] A paper read before the Fellows of the Royal Society of Medicine on Nov. 18th, at the adjourned discussion on Heredity, with Special Reference to Cancer, Tuberculosis, and Disease of the Nervous S

United Kingdom Police Surgeons' Association.—The annual meeting of this association was held recently at 6, Catherine-street, Strand, when the following officers were elected for 1908–09:—President: Mr. H. Nelson Hardy. Vice-Presidents: Sir H. D. Littlejohn (Edinburgh), Dr. H. W. Oulton (Dublin), and Mr. F. W. Lowndes (Liverpool). Treasurer: Mr. J. Paul Bush (Bristol). Honorary Secretaries: Dr. W. H. Whitehouse (Birmingham) and Mr. W. Powell (Cheltenham). Council: Dr. Henry Barnes (Carlisle), Mr. J. M. Harper (Bath), Mr. W. J. Heslop (Manchester), Mr. E. K. Houchin (London), Dr. L. Maybury (Portsmouth), Mr. J. T. J. Morrison (Birmingham), Dr. T. F. Higgs (Dudley), Mr. H. W. Roberts (London), Mr. W. M. Roocroft (Wigan), Dr. C. Templeman (Dundee), Dr. T. Wallace (Cardiff), and Dr. J. F. Craig (Birmingham).

Midland Medical Union: Chesterfield Branch.—On the invitation of the Rev. E. F. Crosse, vicar of Chesterfield, the members of the Chesterfield branch of the above Medical Union attended service at the parish church on Oct. 18th (St. Luke's day). Amongst those who were present were Dr. G. Booth, Dr. J. G. Shea, Dr. D. M. Livingstone, Dr. A. Green, Dr. W. J. Symes, Mr. J. H. Booth, Mr. A. W. Shea, Mr. F. J. Waldmeier, Mr. M. L. Ford, Mr. R. Godwin Chase, and Mr. J. Buckley and the general secretary, Mr. G. S. O'Rorke, LL.D., of Nottingham. The mayor, Mr. Alderman Eastwood; the mayor-elect, Mr. Councillor Short; and the town clerk, Mr. J. Middleton, were also present. The lessons were read by Dr. G. S. O'Rorke (lay reader) and a sermon was preached by the vicar from the text St. Mark ii. 9 to a large congregation comprising over 2000 people.

University of Oxford.—Scholarships in Natural Science are announced for competition as under: Dec. 1st, Balliol College, Christ Church, and Trinity College; Dec. 8th, University, Lincoln, and Magdalen Colleges; Dec. 15th, Jesus College; March 9th, 1909, Keble College; March 16th, 1909, Merton, Exeter, and New Colleges.—In the recent competitions for University entrance scholarships that at the London Hospital was awarded to H. Scott Wilson, Queen's College; that at St. George's Hospital to G. H. Varley, St. John's College; and that at St. Thomas's Hospital to H. C. Bazett, Wadham College.—The degree days in the present term are: Thursday, Oct. 22nd; Saturday, Nov. 7th, at 2.30 P.M.; Thursday, Nov. 26th at 10 A.M.; and Thursday, Dec. 17th, at 10 A.M.—The Examination in Preventive Medicine (D.P.H.) will commence on Tuesday, Nov. 17th, at 10 A.M. Names must be sent in not later than 10.30 A.M. on Tuesday, Oct. 27th. Forms of entry and all particulars may be obtained from the Assistant Registrar, Old Clarendon Building.

Society for Relief of Widows and Orphans of Medical Men.—A quarterly court of this society was held on Oct. 14th at 11, Chandos-street, Cavendish-square, Dr. G. F. Blandford, the President, being in the chair. 19 directors were present. The death of a member of the society was reported. Three new members were elected. It was decided to give to the annuitants of the charity a present at Christmas in addition to their usual grants, each widow to receive £10, each orphan £3, and each orphan on the Copeland fund £5; a sum of £523 was voted for this purpose. Since the last court a donation of £330 had been received from Mrs. Cullingworth, whose husband, the late Dr. C. J. Cullingworth, had been a member of the society. A cordial vote of thanks was passed and a copy of the resolution was forwarded to Mrs. Cullingworth. The directors of the society cannot too strongly urge, especially on the younger members of the profession, the advantages of joining the society, the invested funds of which now amount to £100,000. Membership is open to any registered medical practitioner who at the time of his election is residing within a 20-mile radius of Charing Cross. The subscription is £2 2*s*. per annum, payable in one sum or in two half-yearly sums of £1 1*s*. each. There are special terms for life membership. Full particulars and application form for membership may be obtained from the Secretary, at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

Dr. W. A. Dingle has been unanimously chosen Mayor for the Borough of Finsbury.

Presentation to Professor T. G. Brodie.—At a meeting of the Physiological Society held at Guy's Hospital on Oct. 17th a testimonial was presented to Professor T. G. Brodie, F.R.S., in recognition of his services to physiology and experimental pathology, on the eve of his departure to Toronto where he has received the appointment of professor of physiology. The subscribers to the fund included not only members of the Physiological Society but also numerous old friends and colleagues at King's College, St. Thomas's Hospital, the Embankment Laboratories, the London School of Medicine for Women, and the Royal Veterinary College, in which places Professor Brodie holds, or has held, appointments. The sum subscribed amounted on Oct. 17th to nearly £80, and Professor W. D. Halliburton, who has been acting as the honorary treasurer of the fund, had the pleasure of handing to Professor Brodie a cheque for this amount, less a small sum which was reserved for the purchase of a more permanent memento of the occasion; it is intended that this memento shall take the form of a piece of plate and shall bear a suitable inscription. We understand that the fund is not yet finally closed and that Professor Halliburton (King's College, London, W.C.) will be glad to receive donations from any who may not have received copies of the circular which has been sent out and who may desire to participate in this token of regard for Professor Brodie.

Manchester Infirmary.—The last days of the old Manchester Infirmary have been marked by a gathering of old residents, possibly unique in hospital history. Out of the number of just over 400 medical men still alive who have held resident appointments there no fewer than 260 were present at the gathering held on Thursday and Friday, Oct. 15th and 16th, to bid farewell to their old hospital. On Thursday very successful photographs were taken under the walls of the old building, first of the 214 old residents present and then of those men who had been residents under the old *régime* up to 1878. Later in the afternoon tea was provided in the hospital by the honorary staff and the wards were thronged with former house physicians and house surgeons anxious to see the old place once more. A dinner was held in the evening at the Midland Hotel and here great enthusiasm was shown. Dr. S. Buckley (resident 1859-72) was President and Mr. F. Melland (1841-42), Dr. S. Nesfield (1855), Mr. W. O. Jones (1861-64) and Dr. Anderson (1862-63) acted as Vice-presidents. The tables were arranged in order of seniority, each being marked with a card giving the years of the men who occupied it. In several cases all the men of a year were present and in others only those were absent who were abroad. Besides the loyal toasts and that of "The President," proposed by Dr. H. A. Lediard of Carlisle, the toasts of the evening were "The Memory of the Old Manchester Royal Infirmary" (Dr. John Anderson of London and Dr. Peter Thompson of King's College, London); and "The Prosperity of the New Manchester Royal Infirmary" (Dr. A. E. Finney of Wilmslow and Mr. William Thorburn of Manchester). The excitement of such a large number of reunions of friends did not allow the speakers a good hearing. On the Thursday and Friday the new infirmary was open for inspection, the old residents being taken round in eight parties under the guidance of members of the honorary staff.

Royal College of Surgeons in Ireland.—The winter session in the College School commenced on Oct. 15th. The prizes of the previous session were distributed by the President, Mr. J. Lentaigne, as follows:—Barker Anatomical Prize: £31 10*s*., G. C. Sneyd; special prize: £26 5*s*., Miss I. M. Clarke. Carmichael Scholarship: £15, J. S. Pegum. Mayne Scholarship: £8, T. C. Boyd. Gold Medal in Operative Surgery: R. Adams; silver medals: C. Greer and G. C. Sneyd. Stoney Memorial Gold Medal in Anatomy: H. G. P. Armitage. Descriptive Anatomy, junior: J. Pendiville, first prize (£2) and medal;

traced seldom but sometimes remarkably. I think it is probable that we shall hereafter find that special forms of heredity are associated with other characters in a manner that will make it an aid in distinguishing maladies that are now classed together but for this we must wait.

A third class of diseases in which heredity is operative consists of the so-called functional affections. Some of them vary extremely in degree and baffle attempts to group them so as to discover their relation to heredity. Such are hysteria and the defective nerve strength which may manifest itself in varied ways and which we are all drawn, sometimes against our better judgment, to designate "neurasthenia." Other functional disorders, such as chorea and neuralgia, have relations too complex for the clear discernment of heredity; and migraine, defined as it is, is connected with quite different constitutional states than disease of the nervous system. Two forms of functional disease have been much studied in relation to heredity, epilepsy and insanity. I propose to confine myself to epilepsy, leaving the relations of insanity to those who take part in the subsequent discussion.

Some cases of epilepsy are outside our subject. Those that result solely from organic lesions of the brain, from disease, or trauma, or difficult birth are not concerned with heredity. I confess I have always acted on the belief that the tendency to convulsion in such acquired cases, without other evidence of disposition, may be regarded as not transmissible. I have never hesitated, on this ground, to permit the marriage of a sufferer, and I have not had any evidence to show that I was wrong in doing so, however early in life the damage arose. I do not question the guinea-pigs of Brown-Séquard, but I do question an inference from guinea-pigs to men. But such cases of "organic epilepsy" are rare. They constitute so small a proportion of the cases as to have little influence in statistics of heredity. The difficulties in ascertaining the facts of family histories are vast. Among hospital patients genuine ignorance often hinders. A woman brought her son for epilepsy and denied that any of his relations had had fits. As soon as she had gone out of the room she returned with two of his brothers suffering from them. It had not occurred to her that a brother is a relation. In patients seen in private the stigma supposed to attach to some diseases leads to concealment, which produces actual ignorance in another generation. A middle-aged lady, with an epileptic nephew, denied any neurotic antecedents and was indignant when I told her that three great-aunts had been in asylums. But it was so.

In my own inquiries into the heredity of epilepsy I have limited myself to these two maladies, epilepsy and insanity. I find that in the cases seen in private there is a family history of one or both in 47 per cent., in antecedents and present or past collaterals. The difficulties I have just mentioned justify the assumption that at least 50 per cent., and probably more, really present a family tendency. Among hospital patients the number is not more than 35 per cent., so great a difference does ignorance apparently make. In the facts presented the percentage was taken from 2400 cases, of which 600 were seen in private. Heredity was ascertained in 39 per cent. of 1193 males and 43 per cent. of 1207 females. These proportions are much less than have been ascertained by others who have included a larger number of diseases. It may be well to confine myself to the cases in which a parent suffered. Jeremy Taylor tells us in one of his sermons that "an epileptick son doth often come from an epileptick father." Of the total cases in which inheritance was paternal the father himself suffered in 40 per cent., when maternal the mother suffered in only 36 per cent. HEREDITY IN CANCER.[1]

By E. F. BASHFORD, M.D. Edin.,

GENERAL SUPERINTENDENT OF RESEARCH AND DIRECTOR OF THE LABORATORY OF THE IMPERIAL CANCER RESEARCH FUND.

THE successful application of the comparative and experimental methods appears to be greatly narrowing the field of inquiry and dismissing many explanations of cancer—previously held with good reason—from further serious consideration. Although this is the case, we still know very little as to its etiology beyond the fact that it manifests itself under the most divergent conditions and in such a way that we may have to entertain the possibility of several etiological factors, some of which are external and some internal to the body. To these factors we are only justified at present in assigning an indirect and mediate etiological significance. The most satisfactory explanation of the causation of cancer will probably be that implied by the accurate description of the nature of the transformation of normal into cancer cells when this advance in knowledge shall have been attained.

In surveying the incidence of cancer in the vertebrate kingdom one has been struck by the fact that certain forms of cancer appear to preponderate in different classes. It is, of course, obvious that the incidence of cancer in representatives of the different zoological classes must differ, since, e.g., structures peculiar to mammals are absent in other vertebrates. But if we consider the mammalia themselves, it appears probable that some species are very liable to forms of cancer, from which others even nearly allied are relatively or altogether exempt, as illustrated, e.g., by the variations in the frequency with which cancer of the uterus or mamma occurs. Cancer of the breast, so common in the human female, is also common in the mouse and dog, but practically unknown in the cow, which, however, suffers quite frequently from primary growths of the liver and adrenal. These tendencies are so constant that it is difficult to escape the conclusion that they depend on innate characters which are hereditarily transmissible, and there can be no doubt as to their etiological importance, although we cannot yet penetrate to their meaning.

Even in the same species we meet with similar idiosyncrasies—e.g., in the greater liability of grey than of other horses to melanotic sarcoma. It may, of course, be argued that these peculiarities in the incidence of the disease are determined by peculiar environment, or by the use to which the organs are put in different species, although this would hardly hold for grey as contrasted with other horses, the disease in question affecting only the pigment cells of the skin. If we compare the tame albino mouse with the wild grey mouse the incidence of cancer is parallel in them, although the two varieties live under very divergent conditions; therefore the liability of the mouse to carcinoma of the mamma appears to be due to an innate tendency.

When we compare the large natural groups of vertebrates, or even the species of the mammalia, the grounds on which we may assume that differences in the incidence of cancer are innate and hereditarily transmitted appear safe. But appliances indicated that the suppression of the use of opium implied recourse to other drugs in place thereof; and whether the Foreign Office was in possession of any information to show that this was the case.—Mr. J. A. PEASE (who answered on behalf of Sir EDWARD GREY) said: The prohibition of the general importation of morphine into China except on certain conditions, was agreed to by His Majesty's Government in Article XI. of the Commercial Treaty between China and Great Britain of 1902. The stipulation contained in that Article, that the prohibition should only come into force on all other Treaty Powers agreeing to its conditions, has, however, only recently been fulfilled. The edict has, therefore, no direct connexion with the measures adopted for the suppression of the use of opium. Whether the suppression of the use of opium in China, if successfully accomplished, would have to any extent the effect indicated in the question is a matter on which my right honourable friend cannot express an opinion. It is not implied in the edict.

---

[1] A paper read before the Fellows of the Royal Society of Medicine on Nov. 18th, at the adjourned discussion on Heredity, with Special Reference to Cancer, Tuberculosis, and Disease of the Nervous System.

The Purity of Milk-supplies.

Sir FRANCIS CHANNING asked the President of the Local Government Board whether he had now completed the consultations with the Board of Agriculture as to dealing with tuberculous cows, and was now in a position either to bring in the Milk Bill at an early date or to take prompt and effective administrative action to secure greater purity in the supply of milk to the metropolis and the great centres of population.—Mr. BURNS (by written answer) replied: The matter is receiving attention, but I am not at present in a position to take action of the kind referred to in the question.

Sir FRANCIS CHANNING also asked the right honourable gentleman whether the report of the Royal Commission on Tuberculosis would be immediately issued; and if not, whether, having regard to the constant demands of local authorities for further powers to deal with this disease, whether as affecting the public health or cattle, and to the questions constantly raised by agriculturists, butchers, and others as to the losses caused by the persistence of this disease, he would press the Commission to report promptly and undertake to deal with the whole question of the extirpation of this scourge by national and adequate machinery at the earliest moment.—Mr. BURNS replied: I have made inquiry and am informed that no definite date can be fixed for the issue of the final report of the Royal Commission, but I understand that it is now preparing another interim report dealing with the infectivity of milk from tubercul[illegible] cows which will probably be presented next month. I will bring under the notice of the Commission the de[illegible]ressed in the latter part of the question with regard to its report.

MONDAY, OCT. 19TH.

Vaccination Cases in Cirencester.

Mr. LUPTON asked the President of the Local Government Board whether a medical officer, on behalf of the Local Government Board, had inquired into cases of children vaccinated in Cirencester, and if he ascertained that the result of the vaccination in the case of three or more children had been to cause terrible sores, eating the flesh to the bone; and if, in consequence of these and other similar cases, the quality of the lymph supplied by the Local Government Board had been changed.—Mr. BURNS replied: Three instances at Cirencester which called for inquiry were investigated by one of the medical inspectors of the Local Government Board. In two of them the vaccination places were long in healing, but the symptoms were not of a serious character. A large number of children were vaccinated from t[illegible]mphs used in these cases respectively without any such symptoms and the evidence indicates that in these two cases secondary contamination of the vaccination places occurred. In the third case there was deep ulceration at the site of vaccination. This, however, did not begin to show itself till subsequently to the ninth day after vaccination, and no adverse report has reached the Local Government Board in respect of any of the thousand or more children vaccinated from the same lymph as that used in this instance, although reports are required in each case. The home of the child was insanitary and overcrowded, and it appears to be clear that the vaccination places were secondarily infected by septic material. I am not aware of any need for changing the quality of lymph used by the Board.

Mr. ESSEX: Is the right honourable gentleman satisfied that these cases developed unsatisfactorily owing to the unsatisfactory conditions in which the children were?

Mr. BURNS: Our officers report to us that these symptoms were developed by uncleanliness.

The Destruction of Tuberculous Carcasses.

In answer to Mr. ABEL SMITH, who asked whether the Government was prepared to adopt the recommendations of the Select Committee on Tuberculosis as to compensation for carcasses condemned as tuberculous, Mr. BURNS said: Legislation would be necessary to give effect to that suggestion and I am not in a position to promise that such legislation will be proposed by the Government.

TUESDAY, OCT. 20TH.

The Medical Relief of the Poor.

Mr. SUMMERBELL asked the President of the Local Government Board whether he would state the number of cases in the coroners' returns of starvation cases, respectively, connected with Shoreditch, Holborn, and the whole of London; whether he had taken any, and, if so, what, steps to reduce the numbers in future; and whether he would suggest to the guardians of those unions that they should make it known to the poor that they were willing to give necessary relief, and especially medical relief, to the poor who needed it, in accordance with 43 Eliz., c. 2, s. 1, and 4 and 5 Will. 4, c. 76, so that the poor might apply before they became totally destitute.—Mr. BURNS replied: The latest return of the number of deaths upon which a coroner's jury returned a verdict of starvation or death accelerated by privation shows that in the year 1907 there were 46 such cases in the whole of London, of which eight were connected with Shoreditch and seven with Holborn. There appears to be no reason to suppose that the poor were unaware of the facilities for obtaining medical or other relief. In many of the cases mentioned in the return relief was applied for and given, but the application was made at too late a stage. I will give consideration to the matter, but it is difficult to see what effective action can be taken in respect of persons who are unwilling to apply for relief and whose cases are in no way brought under the notice of the guardians or their officers.

The Disposal of Sewage.

Mr. CLOUGH asked the President of the Local Government Board whether any further reports would be issued by the Royal Commission on the Treatment and Disposal of Sewage; and, if so, how many, and when did he expect to receive the final report; and whether he proposed to introduce legislation for the regulation of trade effluents into public sewers before he received the final report of this Commission.—Mr. BURNS answered: I understand that the Royal Commission proposes to issue a report in the course of the next three months on the disposal of distillery refuse and that in its final report it will deal with the disposal of other trade effluents when not mixed with sewage. The date of the issue of the final report cannot at present be given, but I do not think it will be necessary to await it before proposing legislation on the subject referred to in the question.

Trypanosomiasis and Syphilis in Uganda.

Mr. REES asked the Under Secretary of State for the Colonies how much of the grant in aid of £85,000 from the Imperial Exchequer to Uganda Protectorate in 1907–08 was expended on preventive measures taken against the spread of trypanosomiasis and syphilis; and how much of the like grant of £25,000 to Nyassaland was expended in preventing the spread of the former disease towards the latter Protectorate.—Colonel SEELY (in a written reply) wrote: A sum of about £11,000 was provided in the Uganda estimates for 1907–08 for the purpose of combating trypanosomiasis. An expert was sent out during the same year to report on the question of syphilis. His report has now been received and considered and a sum of £2000 has been inserted in the estimates for the current year for the purpose of providing better and more systematic medical treatment for the natives who are suffering from the [illegible] land, efforts were directed during 1907– [illegible] of trypanosomiasis in the countries bordering on the [illegible] of the various kinds of tsetse fly within the Protectorate. This information appears to be an essential preliminary to any proper scheme of prevention.

WEDNESDAY, OCT. 21ST.

The Inmates of Broadmoor Asylum.

Mr. MARKHAM asked the Secretary of State for the Home Department [illegible] een directed to a speech of one of His [illegible] many murderers were confined in Broadmoor Asylum [illegible] y sane; whether he would say whether the decision of the doctor of this asylum as to whether a patient was insane or not was final; and whether no examination either by a medical board or independent medical man was permitted.—Mr. GLADSTONE replied: I have seen a report of the learned judge's remarks and I think that the honourable Member has somewhat misapprehended their purport; but I may say in reply to his question that there are in Broadmoor persons guilty of murder who could not at the present moment be held to be insane, but who must be detained in Broadmoor in pursuance of the order of the court so long as there is a serious risk that, if set at liberty, they would relapse into the condition in which they committed the crime. In judging of the mental condition of patients I rely on the advice of the medical authorities who see them daily and who have exceptional experience of similar cases, and I should not be assisted by calling in other medical men who, however eminent, could not have the same opportunities of forming an equally trustworthy opinion. In any case, the present mental condition is by no means the only determining factor in deciding whether it is safe to release a man who in a state of insanity has committed a grave crime and who, if at large, might again become dangerous.

BOOKS, ETC., RECEIVED.

A Text-book of Diseases of the Ear. By Macleod Yearsley, F.R.C.S., Senior Surgeon to the Royal Ear Hospital; Medical Inspector to London County Council Deaf Schools; Lecturer on Anatomy and Physiology to the Training College for Teachers of the Deaf, Ealing. Price 18*s.* net.

Tutonish. An International Union Language, under a Liberal Anglo-Saxon Leadership. By Elias Molee, Ph.D. Price 1*s.* net.

great variations in accordance with the frequency of cancer in their progenitors above and below the average given in the preceding table, the division of the population into groups with and without a family susceptibility would be practicable and the investigation of possible hereditary factors feasible in the case of man.

The segregation of the general population into such groups is, however, rendered very difficult, because the great frequency of cancer as a cause of death in adult life discounts very largely any value which might otherwise attach to a succession of cases or to its mere appearance and reappearance in a family as evidence of heredity; the peculiarities of its age-incidence make it difficult to know what proportion of relatives have suffered or would have suffered had they lived long enough. It is not so easy to ascertain how many attained to "cancer-ages" as it is to learn how many relatives, e.g., brothers and sisters, were born. It must be confessed that a segregation of families into those relatively liable to, and relatively exempt from, cancer has not as yet been satisfactorily attained, although attempted repeatedly. It is not difficult to collect a number of family histories of those who have suffered from cancer, but it is difficult to the point of impossibility to make these histories complete genealogical trees for three, and even for two, generations. What is of even more importance is the difficulty[2] of bringing the data for such limited members of families into relation with the population generally in a way which may justify a comparison between them, so as to be sure that cancer is really more frequent in some families than in others.

For the determination of the importance of heredity we are concerned with the comparison of the frequency of cancer in parents and children. It is immaterial whether we reason from groups of cancerous and non-cancerous children to their parents, or from cancerous and non-cancerous parents to their children. What we are seeking for is the evidence of the hereditary *transmission* of cancer and the relation between its occurrence in parents and children will be revealed as well by the one method as by the other if the data can be obtained. The evidence we have to rely on is, I am afraid, of a very imperfect kind and of the following nature. It may be considered under four heads corresponding to a grouping of the data obtained: (*a*) where no history of cancer was obtainable and the family history not properly recorded; (*b*) where no history of cancer was obtainable but the family history was recorded; (*c*) and (*d*) where a history of cancer was obtainable and the family history fully or imperfectly recorded.

In the two years 1906 and 1907 reports on 2932 patients suffering from malignant new growths in which the clinical diagnosis had been confirmed by microscopical examination were received by the Imperial Cancer Research Fund.

I. Of these 2932 cases the space assigned to records of the family history was not filled in at all, contained a record stating that the family history was doubtful as regards the occurrence of cancer in "ascendants" or "collaterals," or showed the family history had obviously been carelessly inquired into in 2263 cases. Therefore, in three out of every four cases there was either no knowledge on the part of the patient that near relations had suffered from cancer or carelessness on the part of the recorder of the incidents in the family history of the patient. It is *a priori* quite intelligible, as many investigators have stated, that the class from which hospital patients are drawn are ignorant of the causes of death and, even of the life-history of their ascendants and collaterals, the exigencies of existence causing them to fall out of touch with the family. The fact that no reliable statement was obtainable for 2263 out of a total of 2932 cases must be in the main referred to these circumstances, or to the circumstance that cancer as a matter of fact had not occurred in the family. The weight which will be attached to these alternatives will doubtless depend upon the bias of the inquirer. Those supplying the information to the Imperial Cancer Research Fund may be looked upon as reliable and unbiased observers and their inability to supply information was in all probability the consequence of insurmountable difficulties in attempting to elicit positive information. Nevertheless, the large proportion of patients corresponding to 4526 parents and a much higher but unknown number of collaterals in whom no evidence of cancer was obtainable is very striking. Even allowing for the imperfections of the records, these figures are an example of the kind of evidence which is advanced to show the occurrence of few cases of cancer in a large number of relatives. There are no data which permit us to deny that the 4526 parents of these 2263 cancer patients actually suffered from cancer in the same proportions as the general population—viz., 1 in 11 men and 1 in 8 women. The same may be said for the collaterals. The fact that no statement was made does not justify the assumption that the incidence of cancer in the parents of these patients was less than in the general population, and we must therefore restrict our reasoning to those family histories in which definite statements as to the occurrence or absence of cancer were made.

II. There remain 669 cases to be considered. It was definitely recorded for 358 patients, the number of whose brothers and sisters was also stated, and who, judging by this fact, were well informed of their family histories that no other case of cancer had occurred in the family. These 358 cases of cancer are therefore to be regarded as sporadic cases without heredity; 358 cases without family taint out a total of 699 families is such a high proportion that if su records are to be relied upon a family taint evidently is n the sole foundation upon which cancer develops.

III.-IV.—Cancer was recorded in one to four blood relativ of the remaining 311 cancer patients. Thus, out of 669 patien suffering from cancer whose family histories were obtainab cancer is recorded as having occurred in the relatives 311—i.e., in 50 per cent. But as we have already seen tl mortality from cancer is so great that in one of two cases cancer either a parent or grandparent will have died fro cancer without assuming hereditary predisposition. Henc the use made of such records to prove the occurrence of large number of cases of cancer in a selected number o families is not warranted.

The 311 patients with a family history of cancer had 35 cancerous relatives. The father was attacked 58 times an the mother 114 times, or 1 in 5·4 for fathers and 1 in 2· for mothers. This appears to be a very much higher rat than occurs in the general population for males and female above 35 years of age. A crude calculation of this kind appears to be the usual method by which the figures for family histories of cancer are utilised to bring out evidence of heredity. In it no account is taken of the families of the 358 cancer patients for whom complete histories were obtained, showing no occurrence of cancer in relatives. If it is, however, not justifiable to exclude them, since doing so appears to beg the whole question, then the 58 cancerous fathers and the 114 cancerous mothers occurred among the 669 male and 669 female parents of cancerous children, or 1 in 11·5 of the fathers and 1 in 6 of the mothers suffered from cancer. These proportions are as near those obtaining for the general population dying from all causes as can be expected from such crude data.

No detailed reference has been made to the numbers of additional cases of cancer recorded in the brothers and sisters of cancer patients, the reason being the very good one that no approximate estimate of their respective ages at death and no comparison with the general population is possible. It gives us no information whatsoever to find that 15 deaths occurred in 607 brothers born and 27 deaths in 596 sisters born, and we are no further if we take the brothers and sisters only of those patients who died over 50 years of age. However, Weinberg has been able to make an approximate calculation for cancer patients in the population of Stuttgart. In order to obtain a basis for comparison he ascertained how many deaths from cancer had occurred in the family of the deceased and also how many deaths from cancer had occurred in the families of their husbands and wives. According to data thus obtained there died from cancer of 100 relatives:—

	Of the deceased.	Of their husbands and wives.
Parents	6 6 per cent.	5 9 per cent.
Brothers and sisters	3 9 ,,	3 1 ,,

And he concludes that heredity does not play a dominant part. We have still to consider the importance attaching to

---

[2] The difficulty is less when the question put is that of contrasting parents with the generation sprung from them, and with certain reservations it may be overcome in this case; but it is a counsel of perfection to assert that the question put should be a comparison between the frequency of canc the total number of relatives of one is a statement of a practi inquiry. The two statements, however, really involve one and the same problem.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—House Surgeons for six months. Salary at rate of £65 per annum.

ISLE OF MAN ASYLUM.—Assistant Medical Officer. Salary £150 per annum, with board, quarters, and washing.

LANCASHIRE EDUCATION COMMITTEE.—Two School Medical Inspectors. Salaries £250 per annum, increasing to £400, with reasonable expenses.

LANCASTER, ROYAL LANCASTER INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging.

LIVERPOOL EDUCATION COMMITTEE.—Two School Medical Officers. Salary £250 per annum.

LONDON COUNTY ASYLUM, Banstead, Sutton, Surrey.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

LUTON, BOROUGH OF.—Medical Officer of Health. Salary £400 per annum.

MARGATE, ROYAL SEA BATHING HOSPITAL.—Resident Surgeon. Salary at rate of £80 and £120 per annum, with board and residence.

MENSTON, NEAR LEEDS, WEST RIDING ASYLUM.—Fourth Assistant Medical Officer. Salary £150 per annum, with board and apartments.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, Grafton-street, Fitzroy-square, W.—Two Anæsthetists.

MIDDLESEX HOSPITAL, W.—Second Assistant in the Bacteriological and Clinical Laboratories. Salary £100 per annum.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior House Surgeon. Salary at rate of £100 per annum, with board, attendance, and washing.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Surgeon Laryngologist.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Third Resident Medical Officer. Salary £60 per annum, with board, residence, [illegible] laundry.

NORFOLK EDUCATION COMMITTEE.—Two Assistant Medical Officers. Salary £250 per annum and necessary travelling expenses.

PAPA WESTRAY PARISH COUNCIL, Orkney.—Public Vaccinator. Salary £90 per annum, with fees and house.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for Out-patients' Department for four months. Salary at rate of £60 per annum, with board, residence, and washing.

ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square.—Assistant Dental Surgeon. Also Joint House Anæsthetist. Salary £30 per annum.

ROYAL NAVY, MEDICAL DEPARTMENT.—Fifteen Commissions.

ST. BARTHOLOMEW'S HOSPITAL.—Assistant Aural Surgeon.

ST. GEORGE'S UNION INFIRMARY, Fulham-road, West Brompton, S.W.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing.

SANITARY INSPECTORS' EXAMINATION BOARD.—Two Medical Officers of Health as Examiners.

SHEFFIELD, UNIVERSITY OF.—Demonstrator in Physiology. Salary £150 per annum.

WARRINGTON INFIRMARY AND DISPENSARY.—Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and laundry.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Ochiltree, in the county of Ayr; at Leuchars, in the county of Fife; at Ballaghaderrin, in the county of Mayo; and at Athlone, in the county of Roscommon. A vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, in regard to lead poisoning cases, for County Court Circuit No. 26 is also announced.

Births, Marriages, and Deaths.

BIRTHS.

CHAPLIN.—On Oct. 17th, at Angmering, Sussex, the wife of Clement W. Chaplin, M.D. Lond., *of a son.*

FORRESTER.—On Oct. 18th, at Bolton-street, Piccadilly, the wife of C. C. Forrester, M.B., Cairo, of a son.

LAWSON.—On Oct. 14th, at Harley-street, Cavendish-square, the wife of Arnold Lawson, F.R.C.S., of a daughter.

MADDEN.—On Oct. 15th inst., at 2, Pierremont Villas, Queen's-road, Broadstairs, the wife of Dr. F. C. Madden (Cairo), of a daughter.

MYERS-WARD.—On the 16th inst., at Kelvin House, Northwood, Middlesex, the wife of C. F. Myers-Ward, of a daughter.

DEATHS.

GLOVER.—On Oct. 14th, at Highbury-place, James Grey Glover, M.D., J.P., aged 76 years.

RIDER.—On the 18th inst., at 16, Garfield-terrace, Stoke, Devonport, Alonzo G. Rider, M.B. (London), M.R.C.S., L.R.C.P., aged 41 years, the elder son of Alonzo J. Rider, J.P.

TREVES.—On Oct. 14th, at Dalby-square, Margate, William Knight Treves, F.R.C.S. Eng., aged 65 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

During the week marked copies of the following newspapers have been received:—*Birmingham Daily Post, Springfield Daily Republican* (*U.S.A.*), *The Carlisle Patriot, Nottingham Guardian, Nottingham Express, Yorkshire Herald, Birmingham Post, Liverpool Post, Manchester Guardian, York Observer, Westminster Gazette, Leeds Mercury, Freeman's Journal* (*Dublin*), *Belfast News Letter, Lincoln Mercury, Taunton Mail, Liverpool Courier*, &c.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL MEN AND RUDYARD KIPLING.

To the Editor of THE LANCET.

SIR,—Referring to the report of Mr. Rudyard Kipling's brilliant and stirring address a few days since to the students of the Middlesex Hospital, perhaps I may be allowed to relate a story as an instance of the heroism which doctors can display under trying circumstances.

I have had the pleasure of meeting and being treated more or less by 22 medical men whose names I could recount, and therefore have had a pretty large experience.

The story is this. One of a large family, I had a younger brother subject to frequent attacks of hæmorrhage from the nose, and in those days the only means of saving such a sufferer from death seemed to be by plugging both nostrils. Indeed, some celebrities called to see the patient, and though they were pleased to call it a "very interesting case" they could not advise any other remedy, though one or two had been tried but failed. I can remember vividly being called up at about 3 or 4 o'clock one dark winter's morning with snow on the ground "to fetch the doctor." When I arrived at his house he put his head out of window, promising to come round as quickly as possible. My little part was to hold one of the lights at the bedside, but noticing that I was about to collapse he peremptorily ordered me to put down the light and go, which I did, and promptly fell into a fainting fit at the foot of the stairs. Recovering myself and meeting the doctor leaving the house, I tried to apologise for my weak behaviour but was told by him that few novices would pass through such an ordeal without the same result. The doctor said he had performed the operation under difficulty and expected we had thought him a little tardy in arriving, but all the time at the operation he had had his clothes pressing upon an abscess, and he had come through the snow and sleet leaving a wife at home in an almost dying condition.

Of course I may be wrong, but I can hardly conceive of more heroic behaviour on a battlefield, where acts such as these might be related in the newspapers to the public; but my story is only known to myself and a small circle of friends. The patient and doctor have passed away, but the patience of the former and the bravery of the latter can never fade from my memory. I may add that an old friend and physician had asked this doctor to make his fees light, as we were not in those days in what are termed comfortable circumstances. The bill arrived, with a graceful note accompanying it, saying the fees could have been made larger, but if we thought the bill too much, he would be perfectly satisfied with anything less we might hand him. I need hardly say that with such a man it was quite unnecessary, as the bill was so ridiculously small, and we insisted upon his taking a cheque for double the amount.

Hoping my story may interest and act as a stimulant to many a student,

I am, Sir, yours faithfully,

Oct. 17th, 1908. AN EASTBOURNIAN.

AN EARLY CLINICAL RECORD OF MYOMA OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—The well-known record in the Gospels of the woman having an "issue of blood" (St. Mark v. 25, St. Luke viii. 43) is proof of the fact that myoma of the uterus was not only known in mediæval times, but that even then it was regarded as a peculiarly hopeless malady so far as medical treatment was concerned. A far earlier record, I believe, exists in the book of Genesis where the well-known clinical signs of a fibroid—viz., sterility for a number of years and obstructed labour—are mentioned and where the occurrence of severe hæmorrhage is strongly inferred. The patient in the case cited is Rachel, one of the wives of Jacob. Married soon after Leah, probably within a week of her sister, it was not until to the latter six sons and a daughter had been born that at last Rachel's hopes were realised and a son was born to her. If we allow a period of at least 10 years for this we shall be well within the probable limit, and during this time her sterility was a constant source of trouble to Rachel (Gen. xxx. 1), and what more probable than that she had had many miscarriages, for we find in her last fatal confinement that her midwife encourages her by saying "Fear not; thou shalt have this son also" (chap. xxxv. 17).

After 20 years in the service of Laban (chap. xxxi. 38) Jacob determines to leave and hastily mounting his wives and children on camels he sets out in secret, Rachel carrying with her her father's household gods. Laban pursues after the fugitives and after seven days' journey overtakes them and demands his teraphim. He insists on searching the tents for his lost treasures and enters the tents seriatim until at last he comes to Rachel's. The fearfully rough ride on camel back, combined with fear and agitation, had in all probability produced serious hæmorrhage or possibly an abortion, for we find Rachel reclining on the saddle or litter on which she had ridden, and making the excuse that owing to the "custom of women" being upon her (chap. xxxi. 35) she cannot rise. It is inconceivable that such an excuse would have been given or accepted for an ordinary menstrual period, but if a serious hæmorrhage had occurred, of which there was ocular evidence not only on her clothing but also on the saddle on which she had been riding, then it becomes apparent why she was not disturbed, for her appearance must have been one to

There are, therefore, constitutional conditions which are favourable, and others which are unfavourable, to the growth of cancer, and they can be induced experimentally at will. An analogous relationship may subsist between the subject of spontaneous cancer and the tumour—e.g., in man. Then the consequences of the circumscribed primary cancerous change would depend upon the condition of the "soil" in which it is taking place, from causes either within or without the body.

In conclusion, with nothing but negative evidence of the part played by inherited constitutional conditions before us, and with positive evidence of the important part acquired constitutional conditions can play in furthering the growth, perhaps the development, of cancer, we shall more profitably spend our time if we frankly seek to ascertain how they are acquired, than if we continue to preach the doctrine that they are inherited and that it is hopeless to contend against them.

THE INFLUENCE OF HEREDITY UPON TUBERCULOSIS.[1]

By ARTHUR LATHAM, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL AND SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON.

OUR knowledge on the influence of heredity upon tuberculosis is not precise. We can do little more than state certain more or less well-established facts and suggest possibilities. We know that the transmission of the tubercle bacillus from parent to child in utero is more common than was at one time supposed, but that it is so rare that it is a negligible factor. Certainly the number of instances in which there is clinical evidence of tuberculosis at birth is small. Thus, Schleuter in 1902 only succeeded in collecting 12 well-authenticated cases in man and 70 in animals. The theory that the children of tuberculous parents are born with tubercle bacilli within their bodies and that these remain latent for years is supported by insufficient evidence. It is in all probability true that several years may elapse between the date of infection and the appearance of definite clinical signs or symptoms, but it is impossible to prove that such infection took place before birth and not afterwards. We find that in the great majority of instances the organs of fœtuses born of tuberculous mothers give negative results when inoculated into guinea-pigs. If we neglect the rare instances of the hereditary transmission of the germ, what view are we take of the theory that the soil is transmitted, that there is a hereditary transmission of predisposition, constitution, or diathesis from tuberculous ancestors to their descendants? Modern knowledge has made such a theory less and less probable, for it is becoming clearer that the dominating factor in the incidence of tuberculosis is the opportunity for infection. We know of no instance of a naturally refractory animal or of an artificially immunised animal which is proof against infection by a sufficiently large dose of a sufficiently virulent strain of tubercle bacilli. Clinical experience leads us to the same conclusion in man. A general review of our knowledge shows that the greater the opportunities for infection the greater are the incidence and mortality of tuberculosis. It is difficult to give clean evidence of this, for the effect of environment cannot be wholly eliminated. Environment, however, merely acts by lowering the vitality and so makes a smaller dose of bacilli effective and diminishes the immunising capacity of the individual. The differing incidence of tuberculosis in different trades and in clean houses as against similar but dirty houses is suggestive of the part played by infection. So, too, is Cornet's investigation upon the death-rate from tuberculosis among certain religious orders devoted to nursing. In a review of 38 cloisters embracing the average number of 4028 residents there were 2099 deaths in 25 years. Of these no less than 63 per cent. were due to tuberculosis. Conversely we know that by limiting the opportunities for infection we can practically limit the incidence of the disease. Bang's classical experiment proves this. This observer isolated the calves born in a tuberculous herd and in this way was able to establish a herd which was free from tuberculosis. The same thing is shown by the effect produced by active preventive measures in man. Of recent years more active preventive measures have been adopted in New York City than in any other great town. As a result there has been a more rapid fall in the tuberculous death-rate in New York than in any great city in the world; and what is of interest to this discussion, there has been a decrease of 40 per cent. in the death-rate in children under 15 from pulmonary tuberculosis and tuberculous meningitis during the last ten years, notwithstanding the extraordinary difficulties—chiefly due to the immigrants—present in New York.

We know that infection can always be effective, no matter what the man's diathesis is, under certain circumstances, and we also know that in animals and in man the capacity for resistance differs in different individuals. Whether this difference of capacity for resistance depends on inherited characteristics or not in some instances, we know that whatever the resistance of a man may be to start with, it can be profoundly modified by various agencies. It is an established fact that a high mortality from tuberculosis in any community is always associated with imperfect sanitary conditions. Again, anything which leads to malnutrition leads to a lowered resistance and in consequence an increased mortality from tuberculosis. This is shown by the increase of tuberculosis which is associated with widespread unemployment and with overcrowded poor districts. Chronic diseases which are characterised by loss of nutritive capacity are stated to be associated with an excessive percentage of tuberculosis. Thus the incidence of tuberculosis is excessive in the insane, and the death-rate from pulmonary tuberculosis in young persons suffering from diabetes is stated to be greater than it is in non-diabetic persons of the same age. The influence of environment or disease would appear to act chiefly by lessening the resistance to infection and to be perhaps chiefly important in its effect upon the course of the disease. Environment in its most comprehensive term lessens the resistance to the disease, and hence it causes a greater number of persons to become victims of the ubiquitous infection. More important still, it reduces the immunising capacity of these victims, and hence persons who under better conditions would have acquired a partial immunity and so have been cured of the disease fail to get well, and by acting as carriers of the infective material lead to an increased incidence of tuberculosis. The influence of environment on the course of the disease was well demonstrated by Trudeau who found that rabbits inoculated with tuberculosis rapidly died if they were kept in a dark damp place, whilst others inoculated in the same way but allowed to run wild usually recovered. Similarly it is stated that efficient drainage of the soil at Salisbury, Ely, and Rugby was at once followed by a reduction in the mortality of pulmonary tuberculosis of 49 per cent., 47 per cent., and 43 per cent. respectively.

The parts played by infection and by environment are important when we come to the question whether persons who suffer from tuberculosis transmit a predisposition to this disease, because it is impossible to say whether these two factors have been given their true value in the various investigations made on this subject. Formerly the medical profession were convinced that a tuberculous taint was transmitted from one generation to another. At the present time our opinions are less dogmatic. If we look at infective disease as a whole we find little evidence on which to base the opinion that predisposition to infective disease is transmitted from parent to child. In syphilis it is true that the disease is transmitted in certain instances to the next generation. Such transmission is less frequent according as the parent has been adequately treated—that is, it varies directly with the degree of immunity acquired by the parent. Further, just as congenital tuberculosis is due to the direct transmission of the tubercle bacillus, congenital syphilis is due to the direct transmission of the spirochæta pallida. Lastly, inherited syphilis in the third generation is not an accepted fact. Those who hold that there is a hereditary predisposition to tuberculosis base their opinion largely, if not wholly, on statistics which purport to show the incidence of the disease—and chiefly of only one clinical form of the disease—in families of a tainted stock as compared with its incidence in families of an untainted stock. Several objections apart from the difficulty of excluding the influence of greater opportunities for infection and the

ence to Cancer, Tuberculosis, and Disea

NORTH-EAST LONDON POST-GRADUATE COLLEGE, *Prince of Wales's General Hospital, Tottenham, N.*

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., Medical Out-patient (Dr. Whipham); Nose, Throat, and Ear (Mr. Carson); X Rays. 4.30 P.M., Medical In-patient Clinic (Dr. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Surgical (Mr. Edmunds); Gynæcological (Dr. Giles). 4.30 P.M., Demonstration:—Dr. G. N. Meachen: Selected Skin Cases.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. Giles). *Clinics:—Medical Out-patient (Dr. Whiting)*; Surgical (Mr. Carson); X Rays. 3 P.M., Medical In-patient (Dr. Chappel). 4.30 P.M., Lecture:—Mr. H. W. Carson: Modern Methods of Treatment of Obstruction of the Large Intestine.

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. J. H. Evans). 2.30 P.M., *Surgical Operations (Mr. Edmunds). Clinics:*—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 P.M., Medical In-patient Clinic (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. Lawrence: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.30 P.M., Special Lecture:—Dr. Rankin: Acromegaly, [illegible] Illustrative [illegible]

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Non-valvular Diseases of the Heart.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—The Treatment of Eczema in all its Forms.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Dr. Tooth: Muscular Atrophy.

FRIDAY.—3.30 P.M., Sir V. Horsley: Surgery of the Nervous System

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), *Chelsea* (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Ophthalmic (2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (28th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.).

THURSDAY (29th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), *City Orthopædic* (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (31st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

conditions of living now prevalent must have played some part in raising the resistance of the nation. Few will, I think, deny that part of this diminished mortality is due to improved medical knowledge and improved methods of treatment. It is unquestionable that a larger proportion of consumptives during this period have been cured in the popular sense of the term than formerly. As we are all infected at some period of our lives this tends to show that we have acquired a greater resistance to the disease. In other words, a larger proportion of sufferers have acquired at any rate a partial immunity to tuberculosis. Is it impossible that these people have transmitted a partial immunity to the disease to their descendants? This view was suggested by Dr. H. Maxon King at the London Congress on the basis of observations on 242 cases of tuberculosis which occurred in his own practice. It has so far received little consideration, but it merits investigation, for if there is any truth in it, it affords suggestive evidence to account for the fall in mortality in nations where adequate preventive measures are taken, and amongst which an increasing number of people are cured of the disease and so acquire for themselves a partial immunity.

Calmette's experiments throw a little light on this part of the question. This observer has shown that if an animal is infected with a dose of bacilli which is just sufficient to cause a lesion with which the animal is capable of dealing and from which it recovers, it is a matter of some difficulty to affect that animal with subsequent larger doses, at any rate of more difficulty than in the case of an animal which is in the first instance given a dose which is sufficient to produce a caseating lesion—that is to say, the first animal has acquired a partial immunity. The same thing is often seen in medical practice; for example, a child who has suffered from tuberculous glands and has got well is less likely, in our experience, than others to suffer from pulmonary tuberculosis in adult life. Man is therefore capable of acquiring a partial immunity to tuberculosis. Can he transmit this? As the immunity is partial we cannot expect much result in one generation if it is transmitted, but a succession of generations of persons with acquired immunity might lead to some transmission. In a community in which opportunities for infection are limited as much as possible and in which adequate medical treatment is rewarded by an increasing proportion of arrested cases—that is, of cases with an acquired partial immunity—it would appear that the incidence of tuberculosis diminishes. In a community in which fewer preventive measures are taken and in which medical treatment produces fewer cases in which a partial immunity is acquired, the incidence of the disease does not appear to show the same steady diminution.

If we look at infective disease as a whole there is some evidence to show that when such a disease has been endemic —as opposed to epidemic—in a community for a long period of time, it tends to become of a milder type. Thus syphilis is held by some to have become, in Sir Jonathan Hutchinson's words, a much less virulent malady in Portugal from this cause. The same thing is held to be true of small-pox, measles, and scarlet fever. Conversely, there is some evidence to show that when an infective disease is introduced to a new community—a virgin soil—it is of a more severe and fatal type than when it occurs in a community which, through many generations, has been accustomed to its prevalence. An example of this is the introduction of measles to the Fiji Islands in 1875. The natives had not previously suffered from this disease and this epidemic produced 20,000 deaths in four months. Another example is the introduction of syphilis to Greenland. So far as tuberculosis is concerned M. Cornil has reported that the natives of Patagonia did not know pulmonary tuberculosis before the installation of the English mission. The missionary's wife suffered from consumption. She collected a number of native children round her who were better fed, clothed, and housed than their brethren. In spite of this "a veritable epidemic of acute phthisis" appeared in their midst. M. Cornil states that the history of colonisation shows many other examples. One further instance is the report that of late years the incidence of tuberculosis has made enormous strides amongst the native population of South Africa who a few years ago were practically free of the disease. It is suggestive in the light of the above that Dr. Shrubsall has found, and my experience is the same, that an Englishman who contracts tuberculosis in the East, such as Singapore or a Chinese station, usually offers less resistance to the disease than the Englishman who contracts it in his own country, in spite of the fact that the consular reports seem to show that in the natives of these countries the disease is of a comparatively mild type.

My purpose has been to show that our knowledge on the subject of any hereditary influence on tuberculosis is far from complete. Certainly the evidence in favour of an inherited predisposition is not sufficiently strong to make me vary my practice of refusing to advise those who have suffered from pulmonary tuberculosis and who have acquired a partial immunity in the process of the arrest of the disease, to refrain from marriage.

A general survey of the whole subject suggests that the following conclusions are not wholly wide of the mark:—

1. The hereditary transmission of the germ is so infrequent that it is a negligible factor.

2. The incidence of tuberculosis depends in the main on two factors—(*a*) exposure to infection, which in turn is governed by the dose received and the virulence of the particular strain of bacillus; and (*b*) the undermining of the resistance of the individual by insanitary conditions and by disease.

3. The more adequate the preventive measures taken in any community the less are the incidence and mortality of the disease.

4. The more adequate the medical treatment—that is, the greater the proportion of persons in whom the disease has been arrested and who have thereby acquired a partial immunity—the less are the incidence and mortality of the disease.

5. As at death we all, or nearly all, show evidence of having at some time been infected with tuberculosis, and as most of us are able to overcome the infection, it is clear that the diminished opportunity for repeated infection, brought about by preventive measures and better medical treatment in this country, cannot wholly account for the diminishing incidence and mortality of the disease.

6. There is some evidence to suggest that the diminishing incidence and mortality of the disease may be in part due to a partial immunity inherited in the course of generations from tuberculous ancestors in whom the disease has been cured.

7. The theory that there is an inherited predisposition to tuberculosis is based on insufficient evidence.

Portland-place, W.

VICIOUS CIRCLES ASSOCIATED WITH DISORDERS OF THE DIGESTIVE SYSTEM.[1]

BY JAMIESON B. HURRY, M.A., M.D.CANTAB.,
PRESIDENT, READING PATHOLOGICAL SOCIETY.

DISORDERS of digestion are usually complicated by the presence of vicious circles. This liability arises in part from the interdependence of the chemical, physical, and vital processes associated with digestion; in part also from the close sympathy between the gastro-intestinal tract and other organs, even the most remote. Disease here sooner or later breeds disease there, action and reaction being in continuous operation. The vicious circles associated with digestion are too numerous to be dealt with exhaustively in a brief paper; but some typical examples will direct attention to the importance of the subject and to its bearing on diagnosis, prognosis, and treatment. For practical purposes a regional classification such as the following will be found convenient[2]:—

Group I., circles associated with the mouth.
Group II., circles associated with the stomach.
Group III., circles associated with the intestines.
Group IV., circles associated with the rectum and anus.

GROUP I.—*Circles Associated with the Mouth.*

To this group belong some circles of interest both to the medical and to the dental practitioner. Oral sepsis,

---

[1] A paper read before the Reading Pathological Society, Nov. 12th, 1908.

[2] I have elsewhere suggested a classification of vicious circles based on their mode of origin (chemical, infective, mechanical, neurotic circles, &c.). Illustrations of most of these will be found below. Cf. Brit. Med. Jour., 1907, vol. i., p. 1104.

Three Lectures
ON THE
PATHOLOGY AND TREATMENT OF DIABETES MELLITUS, VIEWED BY THE LIGHT OF PRESENT-DAY KNOWLEDGE.

Delivered before the Royal College of Physicians of London

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

LECTURE I.

Delivered on Nov. 17th.

MR. PRESIDENT, COLLEAGUES, AND GENTLEMEN,—A faulty metabolism of carbohydrate stands at the foundation of the elimination of sugar that occurs in connexion with diabetes. When carbohydrate food is properly metabolised, it is placed in a position to be applied to utilisation and becomes lost sight of in the system. Not so in diabetes. Here the carbohydrate food fails to pass out of the condition of carbohydrate and filters off from the body with the urine in the form of sugar. To obtain a knowledge of where the fault lies, and what it consists of, it is requisite that we should have a knowledge of what transpires in connexion with the normal disposal of carbohydrate. This matter falls in the domain of physiology, and to physiology we have therefore in the first instance to look, for the groundwork to proceed upon. Such is the position in which physiology stands in relation to the subject to be dealt with, and unless we are here led in a right way, we cannot expect to be placed upon right ground for dealing with the problem before us.

By observation and methodically arranged experimental work, we obtain a knowledge of facts, and by the application of our reasoning power to these facts, we deduce from them governing laws or principles of action. As an outcome of the completion of this

INDUCTIVE METHOD

of procedure, the recognised facts no longer remain as isolated items of consideration, but fall into a correlated series, mutually linked together and fitting in with and supporting the deduction that has been formulated.

With the discovery of a law of action, an insight is given which constitutes a source of power by enabling us, through the agency of a designed modification of the conditions, to bring about a desired result. For instance, whilst nothing was known in the case of fevers, and such-like diseases, about the connecting microbe link standing at their foundation, we could only deal with them in an empirical way, and remained powerless to exert any intrinsic control over them. As soon, however, as their dependence upon the presence of a bacterial organism was discovered, a basis was supplied for a systematic extension of knowledge, which, spreading out in various directions, has vastly increased our power in the exercise of our medical art.

Diabetes constitutes the result of an erroneous procedure connected with the application of carbohydrate to the purposes of life It falls within the province of physiology to reveal to us the nature of the procedure normally taking place, and necessarily we must possess this knowledge before we can stand in a position to comprehend the nature of the error that is productive of the disease. The art of medicine, therefore, which is concerned in rectifying the effects of the error, appeals to physiology for a rational basis upon which to work, and for the attainment of working success, everything hinges upon the soundness or otherwise of the teaching supplied.

At first the disease was only known through the bodily symptoms produced, and it remained, till what may be spoken of as a not far remote date, for sugar to be recognised as an eliminated principle in the urine. Without any guiding conception as to the nature of the disease, it afterwards became empirically found out that

FOOD CONSTITUTED AN INFLUENCING FACTOR

in connexion with treatment. In 1848 our countryman, Dr. Prout, said "the first and chief point to be attended to in the treatment of diabetes is diet." Bouchardat of Paris in 1841 introduced gluten bread and gave cases to show the beneficial effect of its employment in the place of ordinary bread. At this epoch, a great move was made by the announcement in 1848 of Bernard's glycogenic doctrine, which formed the starting point for the active and widespread prosecution of the varied researches which have brought us to the position in which we now stand.

Without the knowledge of why or wherefore, experience, as I have said, had begun to suggest that dieting attended with a restriction of carbohydrate food, produced a beneficial effect as a measure of treatment in diabetes. To this the glycogenic doctrine gave no support, seeing that it implied the passage of the food carbohydrate through the circulation to the tissues in the form of sugar and the production of sugar by the liver when carbohydrate was not supplied from without. Thus it was considered to be an essential condition of life that sugar as a force-producing agent should be constantly flowing through the circulation for the purpose of utilisation by the tissues, and the mode of experimenting then adopted, and relied upon, sustained this view. I need not here enter into the consideration of the fallacious character of the evidence upon which the glycogenic doctrine was built. I have shown in my recent work on "Carbohydrate Metabolism and Diabetes" that the propositions originally formulated can be indisputably asserted to be no longer tenable.

It has been said that, at the time of the promulgation of the glycogenic doctrine, experience had commenced to point to the benefit derivable from the restriction of carbohydrate food in the treatment of diabetes. Reasoning based upon this doctrine now stepped in to exert a neutralising effect. See, for instance, the line of argument adopted by M. Rigodin and quoted in the first edition of my work "On the Nature and Treatment of Diabetes." Because the experimental work of the period had shown, as it was thought, that the presence of sugar in the economy was indispensable to life, M. Rigodin considered it rational to allow a diet in which sugar-forming substances entered largely upon the ground that patients suffering from the disease were losing large quantities of sugar.

The same kind of mischievous idea, as it may be truly styled, is found to have place in certain quarters even at the present time—viz., amongst those who take falsely grounded physiological views as their standpoint instead of the teaching derived from the facts revealed by the actual effect of food on persons suffering from the disease.

In support of this assertion let me refer to the recently published work

OF PROFESSOR VON NOORDEN

on diabetes mellitus. At page 81 of the English translation by Dr. Boardman Reed, 1906, the following words are to be found:—"Secondary over-production of sugar, on the other hand, plays an important part in diabetes. The cells (of the body) are everlastingly hungry for sugar, although they are immersed in a medium which contains an abnormally large amount of it. They cannot avail themselves of this sugar for reasons that have been already discussed. Consequently they are continually signalling for the mobilisation of fresh quantities. Where the carbohydrates of the food and the stored-up glycogen can no longer supply the demand, as is the case in all severe forms of diabetes, then proteid, and, as a last resource, fat are called upon to yield sugar. Thus groups of atoms are claimed for this purpose which are usually of service for other purposes. This process may be designated a secondary over-production of sugar."

Here, verily, is an illustration of the kind of dilemma that the glycogenic doctrine may give rise to. It is assumed under it that sugar in a free form has to be constantly flowing into the system to meet a demand existing for it. It is further assumed that, accompanying this flow, there is a concordant removal of the sugar as it is passing through the systemic capillaries, and that diabetes is the result of an error at this point, leading to a non-consumption of the sugar. Notwithstanding, in the state of things portrayed, the system is over-burdened with sugar and gravely disordered from its presence, it is paradoxically contended that more is wanted, and that the want should be met by the supply of carbohydrate from without, and if not met in this way, that protein and fat are called upon to yield it.

At present I will not pursue this matter further, but will leave it till other questions have been considered, and a more origin, protracted and uncontrolled repose may so derange the gastric functions and affect the general health that all inclination for mental and physical exertion vanishes. The patient becomes pre-occupied with his or her own sensations to the exclusion of other interests and affections. A vicious circle is soon established between the psychical condition and the digestive functions of the body. Gastric hyperæsthesia is frequently met with under these circumstances as Mathieu[12] points out: "La douleur, la diminution du coefficient général de la nutrition, l'inquiétude sur leur santé amènent souvent l'éclosion d'un état de nervosisme. ...... Ce nervosisme ainsi accru est une cause nouvelle d'hyperesthésie stomacale, de douleur plus intense et de spasme du pylore. C'est un cercle vicieux dont les affections dyspeptiques présentent de fréquents exemples."

Various circles are set up between the stomach and the heart, often causing the sufferer acute anxiety. A common one is met where worry or insomnia has led to an irregular and weak cardiac action and hence to congestion and œdema of the stomach and intestines. Dyspeptic disorders follow and further depress the heart, a reciprocal relationship being established between them. If the heart is unsound the disorder is still more readily produced, as Robin[13] has described: "Vous vous rappelez combien les troubles gastriques peuvent retentir sur le cœur sain; à plus forte raison seront-ils capables d'impressionner un cœur déjà malade, quand même ils trouveraient en lui leur origine. Ce cercle vicieux où le cœur malade crée les gastropathies qui retentissent sur lui est extrêmement fréquent et son diagnostic vous évitera bien des erreurs de pratique."

Lastly, one of the gravest of vicious circles accompanies a degenerating myocardium, a circle that may begin imperceptibly and steadily widen until it involves well-nigh every organ. *Vires acquirit eundo.* Gibson[14] thus describes it: "Sooner or later, according to its form and severity, chronic valvular disease with compensation itself disposes to failure, by establishing a vicious circle of slow progressive impairment of the viscera and their great vital functions—the lungs, liver, stomach, bowels, kidneys, indeed the myocardium itself."

Some drugs and food accessories create vicious circles, which from their origin may be termed artificial. Alcoholism, for example, excites gastric irritation and anorexia. This condition is followed by a sense of exhaustion and disinclination for work which tempts to further indulgence. At a later stage the chronic atony and dilatation of the stomach,[15] with the circles that have already been described, are apt to follow, and if the misguided victim still flies to the bottle for relief he but pursues a will-o'-the-wisp that will lure him to destruction. Tea is also associated with a circle, especially when infused long and drunk strong as in Ireland. For the resultant dyspepsia further recourse to tea is the usual remedy, a fresh brew being used to remove the very symptoms that former brews have produced. The morphia *habitué* is ensnared by the toils of a habit-circle from which escape is all but hopeless; for this drug, while satiating the immediate craving, creates an appetite for further indulgence and weakens that self-control without which no salvation is possible. A curious condition sometimes accompanies morphia poisoning due to hypodermic injection. A large proportion of the drug is first excreted into the stomach and intestines; it is then reabsorbed and re-excreted, thus setting up a vicious circle.[16] The injudicious administration of anodynes and narcotics may excite some reciprocal relations. For example, if insomnia, caused by dyspepsia, is habitually treated by opium or chloral a secondary dyspepsia may be provoked which keeps up the insomnia. Again, if in ptomaine poisoning the irritation is allayed by sedatives, when the irritant should be removed by an emetic or a purge, the result may be a prolonged retention and increased absorption of the poison leading to a further use of the sedative.

A mechanical circle may be caused by a stretching of the mesentery across the duodenum in cases of gastrectasis: "In some of the cases of acute paralytic dilatation of the stomach it would appear that the small intestines have been driven downwards and backwards into the pelvis by the enlarging organ, and that the mesentery has been drawn tightly across the duodenum. In such cases, in addition to the stomach, the duodenum is distended to the point at which it is crossed by the mesentery, and a vicious circle is thus established."[17] Albrecht[18] draws attention to a curious circle arising in such cases of obstruction owing to the fact that any water that is imbibed cannot reach the intestines, and consequently is neither absorbed nor quenches thirst. The result is that the unallayed thirst causes more water to be drunk, producing increased distention of the stomach, increased obstruction, and increased difficulty in satisfying thirst.

GROUP III.—*Circles Associated with the Intestines.*

Various circles referred to in Group II. apply *mutatis mutandis* to the intestines and need not be further described. Amongst such are the reciprocal conditions associated with visceral congestion and a failing myocardium, with defective peristalsis and fermentation of the ingesta, with enfeebled nutrition and dyspepsia, &c. Other circles only concern the intestines and are largely dependent on anatomical relations. Ordinary colic caused by the arrest in the bowels of some irritating food supplies a common example; indeed, any cause of increased motor activity of the intestine can set up colic, since "every acceleration of peristalsis in the upper loops causes an accumulation of contents and increased pressure in the adjacent intestine. A *circulus vitiosus* results: the peristalsis increases the stasis above the obstacle and the stasis excites the peristalsis.[19] Again, when a coil of intestine is strangled by a band of adhesion or a hernial ring its lumen is soon distended with blood and products of decomposition. As the resulting tension on the intestinal walls increases fresh coils of gut with their mesentery are drawn into the ring and in their turn strangled and distended. As the ring tightens the distension increases; as the distension increases the ring tightens.[20] A similar condition accompanies volvulus, which both causes, and is maintained by, meteorism.

Another circle is met with in intussusception, where the intussusceptum excites the intussuscipiens to vigorous peristalsis. The peristalsis in turn increases the length of the invaginated intussusceptum, cause and effect acting and reacting reciprocally on each other. In the case of hernia the ring tends to enlarge every time the gut descends, which enlargement facilitates a re-descent of the gut. A strangulated hernia associated with secondary vomiting supplies another example, since the strangulation provokes the vomiting and the vomiting increases the strangulation.

The close connexion between the intestines and the central nervous system is seen in membranous colitis with its frequent nervous complications. In fact, the local and the neurotic condition appear often to play into each other's hands, as Mathieu[21] points out: "Dans la côlite mucomembraneuse ...... il semble toutefois y avoir là souvent un veritable cercle vicieux; le nervosisme et l'affection colique retentissent l'un sur l'autre et s'exagèrent réciproquement." And again: "La côlite, les douleurs qu'elle provoque, les troubles de la nutrition qu'elle amène, sont de nature à créer ou à entretenir l'état nerveux. Le nervosisme à son tour exagère les phénomènes de côlite: c'est un cercle vicieux." Manson[22] has drawn attention to a "vicious pathological circle" associated with sprue, especially as met with in the half-starved populations of Eastern countries. In sprue digestion and assimilation are early affected, leading on to tissue starvation and in time to destruction of the secreting and absorbing mucous membrane of the alimentary canal. "As a result of this destruction ...... digestion and absorption cannot be effected; thus, so far from proving a benefit to the starving, good food and plenty of it does but precipitate death, inducing by its mechanical and chemical effects further irritative changes in the starved and eroded bowel."

sugar into the circulation, it becomes at once proportionately apparent through the medium of the urine.

In the healthy state, the carbohydrate taken into the stomach does not reveal itself either in the blood or in the urine. There may be—say 200 or 300, or there may be 600 or 700 grammes taken, and the condition as regards both blood and urine remains unaltered, although as small a quantity as 1-4000th of the weight of the animal intravenously injected, in a pronounced manner affects them.

In diabetes, on the *other hand*, the carbohydrate *reaching the stomach* is *followed with the same* result as on being intravenously injected. This constitutes

THE ESSENTIAL DIFFERENCE BETWEEN HEALTH AND DIABETES

In the latter, *the* carbohydrate taken as food shows itself in the blood and urine, just as it *does* when *introduced in a* direct manner into the circulation.

Cases of diabetes *present* themselves in which a *certain* amount *of carbohydrate* can be ingested without producing any *discernible* effect. Taken within the specific amount, it follows the course that it does in health and becomes subsequently lost to view. Taken, however, beyond the special amount, the result observed is the production of glycosuria corresponding to the extent to which the carbohydrate has surpassed the extreme amount from which no glycosuria follows. *Up to a sharply* defined point, the carbohydrate taken in these cases behaves *as* it does in *the* healthy subject, and fails to be subsequently recognisable, whilst that which is taken in excess of the defined *point* flows *off in the form* of sugar with the urine just as it does in a bad case of diabetes, and just as it would do if introduced by injection in a direct manner into the circulation.

Here, then, carbohydrate within a certain limit comports itself *as it does under* normal conditions, and beyond the limit, takes the course that is followed in diabetes. An intervening line exists between the normal and the abnormal *states*, and it is *interesting and instructive* to give attention to the *facts* observable *in connexion* with the transition from *the one to the other*. To watch the condition closely, the circumstances should be such as *to permit* of the transition point being discernible. Cases vary much as to where the boundary line denoting

THE *TOLERATION POINT OF* CARBOHYDRATE

lies. The tolerating power may be little, or it may *be considerable*. In either case, the result *is* the same on overstepping the boundary line existing, and in the phenomenon, an explanation is seen of the *modus operandi* of the diet testing resorted to by the physician for the supply of diagnostic information in connexion with diabetes. For the sake of illustration, I will cite the following two examples, which show how quickly the change is wrought, and how marked is the effect that may be produced by a limited amount of carbohydrate.

The subject of *a mild* form *of* glycosuria—*that is*, a person who could *partake* to a fair extent of carbohydrate without passing sugar, partook at breakfast, which was finished at 10 A.M., of fish, some toast, a tablespoonful of raspberry jam, and a cup of tea with one piece of sugar in it. The time *of* his visit to me was 10.15 A.M. At 10 20, he passed some urine, which gave no reaction with *Fehling's* solution. Thinking, however, that sugar would be likely to show itself, I purposely prolonged the consultation and obtained urine again at 10.40. This was found to contain 32·8 per 1000 of sugar. It was, probably, to the sugar *taken*, and not the starchy matter, that the high figures were due, sugar being ready for immediate absorption whilst starch has to undergo a preparatory conversion into sugar. With reference to the figures, it has also to be taken into account that urine having been passed at 10 20, that which was obtained at 10 40 represented secretion *unmixed* with urine secreted before the food was taken. The urine of 10.20 would partly consist of this latter, and probably if it had not been present to dilute the other, a certain amount of show of reaction would have been obtained.

In the other case, the patient, 53 years of age at the present time, has been the subject of diabetes for seven years. During *the last* four years, full restriction from carbohydrate food has been necessary to keep the urine free from sugar. The patient resides in Ireland, and for business purposes comes to London about twice a year, upon which occasions it is usual for him to fall under my notice. I observe from my notes that on Sept. 27th, 1904, night and morning specimens were brought for examination and were found to be free from sugar. Curiosity *had* led the *patient* to take a little toast at *breakfast to* see if it would affect the urine, and I *find it noted* that urine passed a short time afterwards gave a *slight reaction* with Fehling's solution.

Having started with the *trial of* the effect of toast in the manner *mentioned*, he continued to carry it on at his subsequent visits, and I will give the precise results that have been observed. April 11th, 1905, no sugar was found in the night and morning specimen of urine brought for examination, whilst two hours after breakfast, at which a single piece of toast was taken, the urine contained 10·9 per 1000 of sugar. Oct. 9th, 1906, the night and morning specimens brought gave no reaction of sugar. Breakfast *had* been taken at eight, and included the test piece of toast. Some urine was passed at *8.30* and *9.30* and was brought mixed together. It gave a trace of sugar reaction. *Urine* was again passed at 10.30 during the visit, and this was *found to contain* 19·2 per *1000 of sugar*. March 13th, 1907, the night and *morning* specimens *gave no* reaction of sugar. Breakfast with the toast as before was taken at 9.15. The urine collected at 10.10 *contained* a trace *of* sugar, and that passed at 11, 10·9 per 1000. Oct. 8th, 1907, the patient breakfasted in a like manner to previously at 8.15. The night and morning specimens were free *from sugar*. Urine collected at 9.15 contained 7·8 per 1000, and that passed at 10.45, 12·5 per 1000.

This case exemplifies the remarkable steadiness associated with the elimination of sugar in diabetes. Here is a patient who, during a period of observation *extending* over three years, was found to pass no sugar whilst on the *properly* restricted *diabetic* diet, *and almost* immediately after
starchy *food in the limited* quantity named, passed ur
containing a decided amount of sugar. The facts
stand in strict accord with common experience in such case
There is a sharp line limiting *the extent* to which carbo
hydrate can be taken without affecting the urine, and it
within the bounds of possibility for the limiting line to
no variation not only for weeks and *months*, but even fo
several years. There is much diversity in *different*
with respect to where the line stands, but *no* matter wh
may be its position, as long as the carbohydrate tak
falls within the particular boundary existing, the
remains unchanged, whilst *if the* boundary is overst
by ever so little, the urine affords an indication of
fact.

In the instance of the particular case upon which th
remarks are founded,

THE BOUNDARY LINE

comprises the carbohydrate present in *the* diabetic
employed by the patient, *for it must be taken as* understo
that it is impossible absolutely to exclude all carbo
matter, however rigidly framed a diet may be. The amo
of toast that sufficed to produce the results that have
narrated may, from the statement made to me by th
patient, be computed at about 15 grammes, or a little
half an ounce. I find that ordinarily made toast cont
about 28 per cent. of water, and making deduction for
water, *the* 15 grammes will *contain* 10·8 *of* dry
matter, which, reckoned to contain *82* per *cent. of starch*
gives 8·8 grammes as the amount of carbohydrate produc
tive of the effects upon the urine described.

Interposed between the seat of elimination of sugar wi
the urine and the *seat of* absorption of sugar *from*
alimentary canal, we have the contents of the circulat
system. All are agreed upon the point that, in the gly
under consideration, the sugar escaping with the urine
derived from

SUGAR PRE-EXISTING IN THE BLOOD.

What is meant *then* by the appearance of sugar in the urin
is that it was previously present in the blood as a *result o*
the carbohydrate food taken, and, *reciprocally*, it may
said that the *presence of sugar in the blood leads to its pro*
portionate presence in the urine. That the two go togethe
is shown by the effect of the direct experimental introduc
tion of sugar into the circulatory system, and confirmed b
rational deduction from the molecular-sized condition o
sugar and water viewed in relation to the eliminati
process. Unquestionably sugar does not stand apart
other small molecular bodies in escaping

origin, protracted and uncontrolled repose may so derange the gastric functions and affect the general health that all inclination for mental and physical exertion vanishes. The patient becomes pre-occupied with his or her own sensations to the exclusion of other interests and affections. A vicious circle is soon established between the psychical condition and the digestive functions of the body. Gastric hyperæsthesia is frequently met with under these circumstances as Mathieu[12] points out: "La douleur, la diminution du coefficient général de la nutrition, l'inquiétude sur leur santé amènent souvent l'éclosion d'un état de nervosisme. ...... Ce nervosisme ainsi accru est une cause nouvelle d'hyperesthésie stomacale, de douleur plus intense et de spasme du pylore. C'est un cercle vicieux dont les affections dyspeptiques présentent de fréquents exemples."

Various circles are set up between the stomach and the heart, often causing the sufferer acute anxiety. A common one is met where worry or insomnia has led to an irregular and weak cardiac action and hence to congestion and œdema of the stomach and intestines. Dyspeptic disorders follow and further depress the heart, a reciprocal relationship being established between them. If the heart is unsound the disorder is still more readily produced, as Robin[13] has described: "Vous vous rappelez combien les troubles gastriques peuvent retentir sur le cœur sain; à plus forte raison seront-ils capables d'impressionner un cœur déjà malade, quand même ils trouveraient en lui leur origine. Ce cercle vicieux où le cœur malade crée les gastropathies qui retentissent sur lui est extrêmement fréquent et son diagnostic vous évitera bien des erreurs de pratique."

Lastly, one of the gravest of vicious circles accompanies a degenerating myocardium, a circle that may begin imperceptibly and steadily widen until it involves well-nigh every organ. *Vires acquirit eundo.* Gibson[14] thus describes it: "Sooner or later, according to its form and severity, chronic valvular disease with compensation itself disposes to failure, by establishing a vicious circle of slow progressive impairment of the viscera and their great vital functions—the lungs, liver, stomach, bowels, kidneys, indeed the myocardium itself."

Some drugs and food accessories create vicious circles, which from their origin may be termed artificial. Alcoholism, for example, excites gastric irritation and anorexia. This condition is followed by a sense of exhaustion and disinclination for work which tempts to further indulgence. At a later stage the chronic atony and dilatation of the stomach,[15] with the circles that have already been described, are apt to follow, and if the misguided victim still flies to the bottle for relief he but pursues a will-o'-the-wisp that will lure him to destruction. Tea is also associated with a circle, especially when infused long and drunk strong as in Ireland. For the resultant dyspepsia further recourse to tea is the usual remedy, a fresh brew being used to remove the very symptoms that former brews have produced. The morphia *habitué* is ensnared by the toils of a habit-circle from which escape is all but hopeless; for this drug, while satiating the immediate craving, creates an appetite for further indulgence and weakens that self-control without which no salvation is possible. A curious condition sometimes accompanies morphia poisoning due to hypodermic injection. A large proportion of the drug is first excreted into the stomach and intestines; it is then reabsorbed and re-excreted, thus setting up a vicious circle.[16] The injudicious administration of anodynes and narcotics may excite some reciprocal relations. For example, if insomnia, caused by dyspepsia, is habitually treated by opium or chloral a secondary dyspepsia may be provoked which keeps up the insomnia. Again, if in ptomaine poisoning the irritation is allayed by sedatives, when the irritant should be removed by an emetic or a purge, the result may be a prolonged retention and increased absorption of the poison leading to a further use of the sedative.

A mechanical circle may be caused by a stretching of the mesentery across the duodenum in cases of gastrectasis: "In some of the cases of acute paralytic dilatation of the stomach it would appear that the small intestines have been driven downwards and backwards into the pelvis by the enlarging organ, and that the mesentery has been drawn tightly across the duodenum. In such cases, in addition to the stomach, the duodenum is distended to the point at which it is crossed by the mesentery, and a vicious circle is thus established."[17] Albrecht[18] draws attention to a curious circle arising in such cases of obstruction owing to the fact that any water that is imbibed cannot reach the intestines, and consequently is neither absorbed nor quenches thirst. The result is that the unallayed thirst causes more water to be drunk, producing increased distention of the stomach, increased obstruction, and increased difficulty in satisfying thirst.

GROUP III.—*Circles Associated with the Intestines.*

Various circles referred to in Group II. apply *mutatis mutandis* to the intestines and need not be further described. Amongst such are the reciprocal conditions associated with visceral congestion and a failing myocardium, with defective peristalsis and fermentation of the ingesta, with enfeebled nutrition and dyspepsia, &c. Other circles only concern the intestines and are largely dependent on anatomical relations. Ordinary colic caused by the arrest in the bowels of some irritating food supplies a common example; indeed, any cause of increased motor activity of the intestine can set up colic, since "every acceleration of peristalsis in the upper loops causes an accumulation of contents and increased pressure in the adjacent intestine. A *circulus vitiosus* results: the peristalsis increases the stasis above the obstacle and the stasis excites the peristalsis.[19] Again, when a coil of intestine is strangled by a band of adhesion or a hernial ring its lumen is soon distended with blood and products of decomposition. As the resulting tension on the intestinal walls increases fresh coils of gut with their mesentery are drawn into the ring and in their turn strangled and distended. As the ring tightens the distension increases; as the distension increases the ring tightens.[20] A similar condition accompanies volvulus, which both causes, and is maintained by, meteorism.

Another circle is met with in intussusception, where the intussusceptum excites the intussuscipiens to vigorous peristalsis. The peristalsis in turn increases the length of the invaginated intussusceptum, cause and effect acting and reacting reciprocally on each other. In the case of hernia the ring tends to enlarge every time the gut descends, which enlargement facilitates a re-descent of the gut. A strangulated hernia associated with secondary vomiting supplies another example, since the strangulation provokes the vomiting and the vomiting increases the strangulation.

The close connexion between the intestines and the central nervous system is seen in membranous colitis with its frequent nervous complications. In fact, the local and the neurotic condition appear often to play into each other's hands, as Mathieu[21] points out: "Dans la côlite mucomembraneuse ...... il semble toutefois y avoir là souvent un véritable cercle vicieux; le nervosisme et l'affection colique retentissent l'un sur l'autre et s'exagèrent réciproquement." And again: "La côlite, les douleurs qu'elle provoque, les troubles de la nutrition qu'elle amène, sont de nature à créer ou à entretenir l'état nerveux. Le nervosisme à son tour exagère les phénomènes de côlite: c'est un cercle vicieux." Manson[22] has drawn attention to a "vicious pathological circle" associated with sprue, especially as met with in the half-starved populations of Eastern countries. In sprue digestion and assimilation are early affected, leading on to tissue starvation and in time to destruction of the secreting and absorbing mucous membrane of the alimentary canal. "As a result of this destruction ...... digestion and absorption cannot be effected; thus, so far from proving a benefit to the starving, good food and plenty of it does but precipitate death, inducing by its mechanical and chemical effects further irritative changes in the starved and eroded bowel."

by insertion in italics, runs: "*The balance of evidence stands in favour of Bernard's theory.*"

No useful purpose will be served by entering into the details of the argument adduced. What are complacently spoken of, in the aphoristic propositions, as "facts," and "proofs," constitute, in reality, assumptions of the same order as those I have just been considering, and I *do not* admit that a faithful representation is given of the grounds of contention that emanate from me. The whole thing, in fact, stands upon too illusory a footing to permit of any conclusion bearing even an approach to substantiality being deducible.

A derisive footnote against my diction is inserted at p. 337 which I *do not feel disposed* to allow to pass unnoticed. The words of the footnote run: "He (Pavy) considers the intestinal epithelium the first barrier against the passage of *sugar into the blood*; what escapes *this* retention filter (*sic*) being caught up by the liver." I have searched and can nowhere find the solecism alleged to have emanated from me, and the style of expression is not such as I can recognise as belonging to me. I suggest that it has much more the aspect of coming from the writer himself, and possibly "caught up" since his transfer from the Physiological Department at the London Hospital to that at Chicago.

There is one point in the argument that ought perhaps to receive consideration because, from the frequency with which I have seen it referred to, it seems to constitute a stock datum for employment in support of the glycogenic theory. "*Thirdly*," the *text* runs, (p. 336) "the percentage of sugar in the blood of the hepatic is greater than that of the blood in the portal vein when no absorption of food from the intestine is in progress." In the criticism of what I have advanced upon this point, it is contended, that the quantitative analysis of the blood for sugar is a process which is technically very difficult and is subject to a considerable experimental error. Neither of these *propositions* I admit, but am content to let them pass. Then it is argued that if "the liver should add dextrose to the blood of the hepatic vein, the percentage increase *of* sugar thus created could be only very slight, on account of the enormous amount of blood which passes through the organ."

PROFESSOR HALLIBURTON,

whose writings we must all consider, whether agreeing with them or not, as entitled to respect, in his article on the subject of diabetes from the physiological standpoint, in the *Practitioner* for July, 1907, in a similar way deals with my having been unable to find more sugar in the hepatic blood than in the portal blood, saying (p. 3), "Other observers have found an increase in the sugar of the blood leaving the liver, but the estimation of sugar in a fluid rich in proteins is admittedly a matter of difficulty. Even (as the late Sir Michael Foster put it) if the increase is as small as hardly to be detected, it must be remembered that the whole blood of the body passes about once a minute through the liver, so that a very small increase each time would mount up to a large total."

The matter in question bearing

ON THE RELATION OF THE HEPATIC TO THE PORTAL BLOOD,

has become, with the progress of time, to a considerable extent shifted from the position it originally held. In the renowned experiment for showing the *sugar*-producing action of the liver, the animal was killed, and blood was afterwards collected from the portal and the hepatic veins. The two specimens were heated in capsules with sodic sulphate, and clear liquids obtained *for testing* with the copper solution. As a result, the contents of the test tube belonging to the portal blood were seen to retain their original blue colour, whilst those of the other showed the production of a copious orange yellow reduction. Upon this basis, and the fact that the liver gave strong evidence of containing sugar whilst the other organs did not, the glycogenic function was founded. The experimental collection *of blood* by catheterism during life constituted a measure employed by me to show that the hepatic vein blood during life was not in the condition that it had previously been assumed to be from the experimental collection after death. Such was the object of the experiment, and with the portal and hepatic venous blood examined side by side, no *difference* of behaviour was discernible between the two.

In reality, the proposition under consideration amounts to this. Without the supply of any fresh evidence in connexion with the matter, and upon the strength of the assumption that the hepatic venous blood contains more sugar than the portal blood, it is suggested that the amount of difference may be so small as to escape being susceptible of recognition by *analysis*, and yet, on account of the large volume of blood *passing* through the liver, the result might be attended with a large amount of sugar reaching the circulation. The superficial plausibility of this suggestion has produced a widespread effect upon the physiological mind and encouraged the idea that the proposition might in truth be looked upon as valid. The question has not been asked as to what would follow if the suggested passage *of sugar* into the circulation in reality took place.

In *former times*, when it was held that an active disappearance of sugar occurred during the passage of the blood

THROUGH THE SYSTEMIC CAPILLARIES,

the amount of difference in the sugar contents of arterial and venous blood was put down as something considerable. Citing one of Bernard's experimental records, the amount given for the arterial blood was 1·450 per 1000, and for the venous, 0·730, expressive of a loss of half of the sugar contained in the arterial blood in its transit through the capillaries. This is now fully known and *recognised to* be in error. Even by the French school, the *contention of* former days upon this point is no longer upheld. As long as credence was given to a disappearance of sugar in the systemic capillaries, feasibility existed for its passage into the circulation through the hepatic vein, but what is to occur if there is ingoing, as contended for, through the hepatic vein, and not the disappearance that was formerly conceived to be taking place within the systemic capillaries. The only issue that could follow would be accumulation in the circulation and outflow with the urine, *giving rise to glycosuria*, which is exactly what I affirm would constitute the state of things existing if the teaching of the glycogenic doctrine were actually carried out.

It must be borne in mind that the amount of sugar that would have to pass into the circulation from the hepatic vein

IF THE CARBOHYDRATE OF THE FOOD HAD TO BE TRANSPORTED

in the form of sugar through the circulation to the tissues for utilisation, would *oftentimes* be very great, and yet it is not found that any manifest show of it is to be recognised in the blood and in the urine. For instance, in connexion with the standard *daily* dietaries previously referred to, it was mentioned that the carbohydrate might mount up to 700 grammes. Now, whether the condition is viewed at a period *of fasting*, on animal food, or on a diet containing either a small amount or a large amount of carbohydrate, the state of things in relation to sugar in the blood and in the urine may be said to be practically the same, but how is this possibly reconcilable with transport through the circulation in the form of free sugar. When the carbohydrate of the food reaches the circulation in the form of sugar, as it obviously does in *diabetes*, the sugar is recognisable alike in the blood and in the urine, and in the state of health, I contend that the result would be the same if the carbohydrate *of the food* were similarly permitted to reach the circulation as sugar.

In the face of these considerations, it seems to me unquestionably evident that the carbohydrate of the food cannot pass into the circulation as sugar, as it is alleged *to do under* the glycogenic doctrine. The writer of the article in Hill's "Recent Advances in Physiology," to which reference has been made, sees the difficulty in *relation* to this point involved in the doctrine, and reckoning up the carbohydrate contained in the liver, blood, and tissues, states that it does not stand in accord with the absorption that may occur from the food, and admits that it must be concluded that a considerable amount becomes converted into fat or incorporated with proteid (p. 314).

As regards

THE LIVER, WHICH UNDOUBTEDLY PLAYS A PART

in checking the passage of sugar into the general circulation, (I have spoken of the organ as affording a second line of defence against the entry of sugar into the system, functionating upon the sugar that escapes being dealt with at crystals, no matter how big, which do not contain colloids may correctly be called gravel; and the most minute calcareous formation which by a laminated structure proclaims the presence of colloidal cement may properly be termed a stone. As the weight of concretions, which by virtue of their chemical composition must rank as calculi, may thus vary within wide limits, it is essential to the comparing of instances of multiple vesical calculi to know not only the number but also the weight or bulk of the stones. So far as is possible these data are given in the summary of cases which follows, but omissions are unavoidable owing to the incompleteness of many of the records.

The description "multiple vesical calculi" must be rigorously restricted to cases in which the simultaneous occurrence in the urinary bladder of two or more stones can be conclusively demonstrated. Instances of the coexistence of two stones are comparatively common; three,[5–8] four,[9–12] and five[13–16] are scarcely noteworthy unless of large size or removed under special circumstances; six,[17–20] seven,[21–24] and eight[25–28] are relatively rare, and examples of more than eight are so few as to merit a brief summary of those I have found in the extensive literature at my disposal here in Cairo.

Bellamy[29] records a case where there were 1 large and 8 small mulberry calculi; Godlee,[30] a chain of 9 stones—6 in the bladder, 2 in the prostatic, and 1 in the bulbous urethra; Raymond Johnson,[31] 3 fragments and 9 acicular phosphatic calculi, of which the largest was 7-8ths of an inch long; Smith,[32] fragments of between 10 and 15 separate stones which varied in size from that of a bean to that of a chestnut; Buckston Browne,[33] 12 uric acid "calculous masses," weighing 200 grains, which "arose from the spontaneous fracture and reunion of multiple calculi"; Sinclair Brown,[34] 14 uric acid stones, the largest 105 grains, the smallest 40; Thomas,[35] 15 uric acid stones, weighing 140 grains; and Brugnatelli,[36] 16 stones of about the size of small peas, composed of calcium carbonate. Sir George Humphry[37] refers to a specimen of 16 vesical calculi now in Guy's Hospital Museum and mentions a case, also of 16 stones, within his experience. Mansell Moullin[38] records an instance of 18 separate uric acid calculi in a man who previously had singly passed 5, and D'Estrées[39] one where the fragments arising from the spontaneous disintegration of a large stone formed the nuclei of 22 other stones: Keyes[40] cites Groves's case of 25 calculi but gives no details; Plowright[41] found post mortem 25 uric acid stones of which 4 were intact and 21 fragmented. Freyer[42] records an example of 25 also; Rivington,[43] of 26; Reginald Harrison,[44] of 35, weighing 660 grains; Thompson,[45] of 40 composed of uric acid; Brugnatelli,[46] of 48 small pea-like stones consisting mainly of calcium carbonate; Erichsen,[47] of 50 of uric acid, weighing 900 grains; Shattock,[48] of 50 also, probably prostatic, the largest being 2 centimetres in its longest diameter; Littlewood,[49] of 60; and Innes,[50] of 105, weighing altogether 3 ounces 69 grains, which he found post mortem in a case of peritonitis. Guy's Hospital Museum contains a specimen (No. 2213) of 142 ammonium urate stones, all of the same shape—cubes with rounded angles—removed by Sir Astley Cooper[51]; Physick's cases[52] [53] of 117, 242, and 307, calculi are widely quoted, but no data are given of the size of the stones; the same surgeon extracted over 1000 calculi,[54] none of which were larger than a small bean, from the bladder of Chief Justice Marshall of the Supreme Court of the United States. Murat[55] found 678 stones in the bladder and 1000 in the kidneys of an old man. Foster[56] washed out of a bladder "between 300 and 400 stones, some as large as a small pea and one the size of a bean"; "the bladder contained altogether over 1000 calculi." Smith[57] had a case in which there were several thousand pisiform uric acid calculi of a total weight of 3 ounces, and Ellis Blake[58] removed post mortem a woman's bladder "which was distended to about the size of a small fist, full of stones about the size of duck shot. …… They were not counted." Heath mentions a case of 200 faceted calculi (? perineal) in the *Indian Medical Gazette* (Vol. XXXVIII., p. 201).

In addition to these there are cases of recurring multiple vesical calculi which have been recorded by Buckston Browne (two),[59] Bruce Clark,[60] and Thomas.[61] In one of Buckston Browne's cases there were removed by suprapubic lithotomy at successive periods from the same patient: first, several (total weight 114 grains); next, three (total weight 46 grains); then one; then another; and lastly, a small sacful of stones which consisted of uric acid and phosphates.

My case is, so far as I can ascertain, unique. The specimen is now in the Museum of the Royal College of Surgeons of England. The total number of stones was 122; their weight, 459 grammes (16 ounces 95 grains); and their volume, 264 cubic centimetres. The single large stone was oval, grayish white, and fairly smooth. It weighed 119 grammes (4 ounces 22 grains) and measured 60 millimetres in the long diameter and 48 millimetres in the short. It was broken before extraction; on pressure being applied by forceps a friable outer shell separated in large fragments, leaving a central, slightly harder core, built of laminæ which were of similar chemical composition but of various densities. As it was approximately of the same composition as the small stones and equally as friable its large size must have been due to a comparative freedom from friction which it probably enjoyed, not only from its partial encapsulation by the bladder wall but also from its being the first formed. In this connexion the absence of facets from its surface is noteworthy.

The small stones varied considerably in size, the largest 6¼th grammes (96 grains). 11 weighed more than 5 grammes (77 grains); 10 more than 4 grammes (62 grains); 15 more than 3 grammes (46 grains); 26 more than 2 grammes (31 grains); 54 more than 1 gramme (15 grains); and 5 more than 0·5 gramme (8 grains). They were mainly white but many were tinged with gray and yellow. Their other physical characters were chiefly the result of their number; they had a tendency to a rectangular plan with rounded ends and angles and, in addition, many were concave-convex. By friction at numerous points of contact each stone had become much faceted. Constant rubbing also had made them dense and smooth, and although some were dull and lustreless many were highly polished and a few were even eburnated. As none showed any evidence of fracturing nor even of roughening of their surface, and as four I examined were not laminated, excepting that the outer layer was the denser, I thought each stone had had an independent origin. Moreover, their water-worn appearance and rounded borders also seemed to render improbable their common origin from the spontaneous disintegration of one or more large calculi. The following are the notes of the case.

An Egyptian fellah, aged 28 years, came to Kasr-el-Ainy Hospital on April 28th last complaining of painful micturition, blood in the urine, and a hard lump in the perineum. The pain had been present intermittently for about five or six months and the blood for several years, during which time small stones had frequently been passed per urethram. The perineal mass first appeared about April 15th and rapidly increased in size; at the same time, micturition became acutely painful and the urinary stream diminished to an incontinent trickle.

On examination a smooth, round, tender, non-fluctuating, hard, almost immoveable mass, of the size of a walnut, was felt in the middle line of the perineum about one inch in front of the anus. Per rectum, another much larger mesial mass, hard, smooth, globular, and slightly mobile, was found anteriorly; it could also be felt on deep palpation above the symphysis pubis but there was no bulging of the anterior abdominal wall. The urine was scanty, blood-red, alkaline, and of a specific gravity between 1015 and 1020: it contained blood and pus in considerable quantity and many bilharzial ova. The patient was somewhat emaciated and anæmic, the lungs were emphysematous, but otherwise the physical examination was negative. The passage of a sound was difficult: it proved the perineal tumour to be a stone or stones distending the urethra, and completely occupying its lumen except for a central canal large enough to admit a medium-size sound. The mass in the bladder also was found to be calcareous. The movements of the sound within the bladder cavity were very restricted.

On April 30th lateral lithotomy with a curved staff was performed; the constituents of the perineal tumour, three faceted white, smooth stones, were first removed from the urethra; the bladder was then found to contain quite a quarry of stones, loosely cemented together by a somewhat granular easily friable powder, so as to form a globular mass. There appeared to be no bladder cavity; the bladder wall was closely contracted around the tumour, forming a shell which seemed as if glued to the outer layer of stones. The von Noorden's work on Diabetes Mellitus, that the author announces himself to be an advocate of the restricted diet treatment of diabetes. At p. 173, he says, "The first rule that I must lay down is this: the reduction of the glycosuria to the smallest possible limit must be the goal that is never to be lost sight of." Again, at p. 180, after having, in the case of mild forms of glycosuria, advocated commencing the treatment with the restricted diet, notwithstanding even the existence of a certain amount of tolerating power of carbohydrate, and stated that carbohydrate is afterwards to be gradually added to the food, he proceeds: "Care must, of course, be taken that the amount always remains below the level of the toleration limit."

Although thus expressing himself upon principle of action in a manner to which no exception can be taken, what do we find amongst his practical recommendations? That the "oat cure" is added to the longish list of special food cures that have been introduced. In the course of my experience, I can recall the introduction of the "treacle cure," the "honey cure," the "skimmed milk cure," von Duering's "rice cure," and Mossé's "potato cure," as food cures for diabetes. To the list is now added

VON NOORDEN'S "OAT CURE,"

and the claim is made for it that it is superior to the other cures. At p. 195, the statement occurs: "In comparing the potato cure and the oat cure, as I often did for the sake of comparison in the same patient, allowing the one treatment to follow the other, I became convinced of the decided superiority of the oat cure. Severe cases of diabetes react much more favourably on oats than on potatoes. I must, however, acknowledge that there are exceptions, and in appropriate cases [the kind of case to be appropriate is not mentioned] I myself have gladly made use of Mossé's treatment."

Comment is made on the effects of the cures being peculiar and paradoxical, and the limitation of the carbohydrate to *one particular* kind is referred to as constituting an underlying principle. "It would seem," says von Noorden, p. 195, "that the diabetic organism is able—temporarily at least—to regain the power of assimilation for one particular carbohydrate, while still unable to utilise the infinitely smaller amount of the various carbohydrates contained in ordinary food. In my laboratory," he continues, "we have tried to discover whether under the circumstances mentioned particular diastatic or antidiastatic ferments, which effect only one particular carbohydrate, occur in the blood; but the investigations, so far as they have gone, have yielded no positive results. We are obliged to leave to the future the elucidation of this practically and theoretically important question."

I am entering to the extent I am doing into this subject because the name of von Noorden is authoritatively associated with the subject of metabolism and is therefore calculated to exert a weighty influence on the medical mind in connexion with the matter that is under consideration. I must confess, however, that I cannot understand how such a proposition as is set forth above could have emanated from the quarter it has done. The whole thing, as it stands, is a medley of misconceptions and incongruities. What can diastatic or antidiastatic ferments in the blood have to do with the particular kind of starch that may happen to be taken? Starch does not reach the blood. No matter what kind is taken, all are agreed that the starch molecule, whatever its source, is hydrolysed into dextrose preparatory to entrance into the system. How, then, can the source of the starch bear on the question of the utilisation of carbohydrate occurring within the system? Utilisation seems to have been mixed up with the prefatory breaking-down process needed to permit of the passage of the carbohydrate into the system. Speaking upon the strength of my own experience, I can unhesitatingly say that I have seen nothing to lead me to consider that there is ground for surmising that one kind of starch behaves differently in the system of the diabetic from another. Indeed, it would be altogether contrary to rational expectation that it should do so

As regards starch and sugar, the circumstances are different. Starch having to undergo transformation before absorption can occur, it is natural to conclude that it is placed in a position to be prevented entering the system as rapidly and freely as sugar, which is in a fit state for absorption at once. As a matter of fact, it is observable that glycosuria can be produced in the healthy subject by means of copious sugar ingestion, whilst it is possible, it seems, for starch to be tolerated to any extent without the production of glycosuria.

A large amount of fallacy is found to be mixed up with various matters connected with diabetes. Let us see how the "oat cure" stands in this respect. The origin of the oat cure is thus narrated by von Noorden (p. 190). "A few years ago I introduced the so-called oat cure into the treatment of diabetes. It was quite accidentally that I came to recognise its significance. A few patients in my clinic were suffering from severe disturbance of the stomach and intestine. I therefore permitted them nothing but oatmeal gruel. To my surprise the glycosuria did not increase, but became much less than it had been upon the very strict diet."

Now, what did the very strict diet include? We are told that it included the gluten food of Rademann of Frankfurt, mentioned in Table 1 (p. 199), which, it is stated, may find a place in even the most restricted dietary, and which the majority of diabetic individuals may have as much of as they may desire.

It has been my custom for very many years past to have the diabetic foods, foreign and otherwise, that I have been able in the course of practice to come across, analysed for the determination of their carbohydrate content, so that I might keep *au courant* with respect to knowledge of the nature of the supply obtained by patients. As a result I have a large collection of reports from which I often derive much serviceable information. In this way it happens that I have a record of analyses of samples of Rademann's food. The analyses were made a few years before von Noorden's work was published, and, therefore, are probably representative of the food actually referred to by him. One consisted of "diabetic white bread" examined in July, 1900. Taken in the water-free state, it contained 73·4 per cent. of starch. A sample of Zwieback (rusks), examined in March, 1898, contained 72·1 per cent. of starch, and another, examined in November, 1902, 64·8 per cent. of starch.

Where is the strict diet character to be found in connexion with these foods? The figures given for starch in ordinary wheaten bread in the water-free state, to which, for permitting of proper comparison to be drawn, all foods should be brought previous to analysis, run from about 85 to 90, or a little over, per cent. Oatmeal is known to contain less starch than wheaten flour, and the amount may not be greater, if it is not even less, than in the bread-stuff food belonging to the so-called restricted dietary of Professor von Noorden. Actual analysis in the accustomed manner has yielded the following figures:—Quaker oats 69·7 per cent., oatmeal groats 73·2, Scotch oatmeal 74·2. Hence, in the nature of things, there would be no justification for the surprise stated to have been experienced that the oatmeal food did not produce a greater glycosuria than what had been noticed to exist under the so-called very strict diet.

The illusory character of much of what is sold under the denomination of diabetic food has been the source of an immense amount of harm, not only from a practical point of view in connexion with the treatment of diabetes, but likewise through the erroneous impression brought to bear on our mental conceptions relative to the disease. It is easy to understand how readily false conclusions may be framed upon points connected with the disease by assuming a food to be constituted otherwise than it really is. I will leave this subject now but shall have occasion later to refer to it again.

The next point to which I will give consideration is the

STATE OF THINGS FOUND TO EXIST AFTER CUTTING OUT THE LIVER

from the blood circuit. Looked at in relation to the view taken under the glycogenic doctrine, the effect of the operation ought to be attended with the production of glycosuria after the administration of carbohydrate food. Special experimental procedures have been adopted for attaining the desired object, and let us see the nature of the result that has been obtained.

Minkowski, taking advantage of the anastomosis existing in birds between the portal and renal veins, as long ago as 1886,[1] experimented upon geese in relation to the point. It is found, through the anatomical condition existing, that the disease. The important part which the pancreas plays in carbohydrate metabolism is too well known to require elaboration, and the pancreatic reaction bears on carbohydrate metabolism. In 1904 Cammidge concluded from his investigations that in inflammatory lesions of the gland there is excreted by the kidneys a substance which on hydrolysis yields a body giving the reaction of a pentose. The results of my investigation, based on over 250 analyses, were published in the *British Medical Journal* in April, 1908. Since that time I have extended my observations very considerably, having now examined the urine of over 500 patients who were personally examined and also that of a number of others whose clinical history I know. My later results have not furnished any data which lead me to modify the general conclusions I then formulated, which were summarised as follows:—

---

[1] Archiv fur Experimentelle Pathologie und Pharmakologie Band xxi., S. 41, 1886.

[illegible] sion arrived at by Mayo Robson and [illegible] and important relationship between [illegible] ne and disease of the pancreas. My [illegible] idge in so far that I have recorded a [illegible] positive results in cases similar to those that may have been included in that author's list of control cases. Cammidge found in a group of cases described as miscellaneous—other than those having a direct surgical interest in relation to disease of bile ducts and pancreas—that four only out of 92 gave a positive reaction. The higher percentage of positive results recorded in my series may possibly be due to the fact that I made use of many serious medical cases of a nature commonly associated with advanced arterial disease, and chronic catarrhal conditions in the intestinal tract, conditions that are frequently attended with degenerative or inflammatory changes in the pancreas and other glands. My results lead me to divide the cases in which the pancreatic reaction was present in my series in the following groups:—

1. A group in which there was definite clinical or pathological evidence of serious organic disease of the pancreas—for example, acute and chronic pancreatitis, usually associated with disease of the bile ducts.
2. A group in which the reaction in the urine is associated with pronounced arterial sclerosis, a condition usually accompanied by more or less sclerosis in different glands.
3. A group in which the reaction is dependent on congestion and catarrhal conditions of the gland ducts and substance, with associated toxæmia—for example, advanced heart disease, appendicitis, pneumonia, malaria, and the like.

This division is, it is hardly necessary to add, somewhat arbitrary, as most cases are in all probability of mixed origin. If these facts are kept in view, and this urinary reaction is carefully studied along with the other clinical features of a case, I have no hesitation in saying that this new test will prove of great value both to physicians and surgeons in the diagnosis and treatment of pancreatic disease.

As I have on a former occasion given a demonstration of the end reaction of this test I do not intend to dwell further on it. I would, however, draw attention to the practical importance of recognising the degree of the reaction in any given case. This is referred to in my paper. More significance necessarily attaches to an abundant deposit than to the presence of a few crystals which are only determined by microscopic examination.

Clinical types of pancreatitis.—I wish it to be clearly understood that I am excluding from consideration those cases of acute pancreatitis in which the clinical features closely simulate those of acute intestinal obstruction, fulminating appendicitis, and the like, cases which tend to a fatal issue in 48 hours or so if not relieved by operation. I am here only concerned with the clinical features associated with the mildly acute, the subacute, and chronic forms of inflammation of the gland. Cases can be conveniently divided into two groups, those in which jaundice is a prominent symptom and those in which jaundice is absent. A striking point in the clinical picture of pancreatic disease is its protean character. The clinical features of an advanced case may closely simulate those of severe or pernicious anæmia. Cases are on record in which this mistake has been made, and in my series I have seen one case of advanced, and afterwards fatal, pancreatitis in which the general appearances of the patient and of the blood were similar to those of pernicious anæmia. In the earlier stages the clinical features may simply be those of slight indigestion, sometimes associated with neuritic-like pains in the limbs or trunk. Yet again, as in the patient shown this evening, the chief symptom is physical weakness with little or no obvious morbid appearances; in this case in all probability the detection of glycosuria prevented a diagnosis of malingering. Progressive cases tend to a fatal issue, and there is reason to believe that many cases which have died from supposed deep-seated malignant disease in the region of the pancreas have been cases of pancreatitis. The clinical features are perhaps better described in the form of records of actual cases.

CASE 1.—A woman, aged 47 years, was admitted to Professor J. Chiene's ward in February, 1908, complaining of pain in the region of the stomach of about 18 months' duration. The salient points in her history are as follows. About 18 months before admission to hospital, when preparing to go out for a walk one day after dinner she was suddenly seized with acute pain in the region of the stomach, causing her to double up and remain in bed for a day. After some hours she vomited some yellowish-green fluid. About a month later she had a similar, though less severe, attack, and in the next 12 months she had eight or nine similar seizures, the attacks gradually increasing in severity, being later accompanied by pale stools, slight diarrhœa, general weakness, and more or less constant abdominal pain. An important point in the previous history is the fact that she has all her life suffered from bilious attacks, characterised by sickness, vomiting, and headaches of sufficient severity to confine her to bed for a day. On examination the patient was a well-nourished stoutish woman, presenting no obvious morbid appearances, with the exception of a wearied expression when the face was seen in repose. The pain complained of was referred to the epigastric region, at times radiating to the left. On palpating the abdomen a definite tumour was palpable in the region of the pancreas, the swelling being irregular in outline and hard in consistence. The liver, the stomach, and the other viscera appeared to be normal. The stools were large, imperfectly formed, somewhat pale in colour, distinctly fœtid, and chemical examination revealed an excess of fat, which, however, was not pronounced. No muscle fibres were detected on microscopic examination. Examination of the urine revealed a pronounced pancreatic reaction with slight glycosuria, the presence of glucose being confirmed by the fermentation test.

At the operation Professor Chiene found that the tumour was an enlarged and indurated pancreas, the surface of which showed numerous small white areas, resulting from previous fat necrosis. A thorough examination of the liver, gall-bladder, and larger bile-ducts revealed nothing abnormal and the abdomen was stitched up without further operative interference. Three weeks after the operation the patient had an attack of abdominal pain accompanied with marked diarrhœa, jaundice, and some febrile disturbance, these symptoms disappearing within eight days, and the patient was soon discharged. Eight months have elapsed since the operation and through the kindness of Professor Chiene I have been able to show you the patient this evening. Her condition has greatly improved since the operation; she has only had one slight attack and she has been almost entirely free from her old bilious attacks. She takes three moderate meals of a mixed character daily and is free from any symptom of digestive disorder. She still, however, complains of a feeling of marked general weakness, accompanied by a prickly feeling across the upper part of the abdomen and a sore feeling in the corresponding region posteriorly.

The next case to which I refer is representative of a group in which the clinical features pointed to deep-seated organic disease in the region of the pancreas, with no palpable tumour, and the case is instructive as showing the value of the pancreatic reaction in distinguishing between chronic pancreatitis and malignant growth.

CASE 2.—A man, aged 64 years, a railway porter, was admitted to the medical ward in the Royal Infirmary under the care of Dr. R. W. Philip in May of this year complaining of weakness, pain in the stomach, and jaundice. The weakness and pain had existed for three months, the jaundice being of from two to three weeks' duration. On admission the patient was somewhat emaciated and markedly jaundiced. The bowels were constipated, the motions being large and clay-coloured; and the urine contained much bile pigment and a trace of albumin. Physical examination of the abdomen gave negative findings; the liver was not enlarged, the stomach and intestines appeared to be normal, and nothing unusual was detected on deep palpation over the region of the pancreas. The clinical features led Dr. Philip to diagnose the condition as one of deep-seated organic disease of the pancreas, probably malignant, with secondary implication of the liver and bile ducts, and at his suggestion I examined the urine twice. On each occasion the pancreatic reaction was negative. This result strengthened the diagnosis of malignancy, and since this was confirmed at the post-mortem examination we have here a confirmation of Mayo Robson's view that the pancreatic reaction has distinct value in differentiating between chronic pancreatitis and from it. I think the tendency is not directly proportioned to the severity of the primary disease. There must be very many instances of several members of a family suffering from diphtheria and it is most important that the records should be so kept as to facilitate observation of the disease in another generation of the same family. Such search will be necessary in the case of many diseases and will involve a special method of indexing; nothing can be achieved unless it is begun.

It would be wearisome even to enumerate the maladies from which we cannot hope to obtain knowledge but I may mention one class of disease on which we may hope for some facts. Though they are not primarily of the nervous system they often affect it gravely. There are those that consist of deranged chemical processes in the vital laboratory of the human frame giving rise to endogenous toxins. We see it in the nerve disturbance which occurs in diabetes, probably due to other material incidental to that by which the excess of sugar is produced, whether or not it is the same as that which often causes death. The heredity of diabetes is familiar but its thorough study is a difficult task. A child not seldom suffers before a parent. The endogenous poisons of what we call gout are certainly many and some also occur without this constitutional state. Both kinds may cause symmetrical symptoms in the extremities but of their nature we know nothing. It cannot be doubted that the processes of the body are largely influenced by heredity.

The cases of disease of the nervous system in which the influence of heredity is marked seem to fall in certain classes. One of these consists of the early abiotrophies. I proposed this term some years ago[1] as a convenient designation for the cases in which certain systems of structure in the nervous or muscular system have an essential defect of vital endurance, in consequence of which their life slowly fails. A marked example is presented by the hair follicles of the scalp, in consequence of which early and extensive baldness occurs in father and son, a convenient subject for the study of heredity. It is seen in the nervous system, as in hereditary optic atrophy, in which the onset is sometimes excited by some extraneous cause, inadequate alone to cause the enduring effect. Hereditary ataxy, or Friedreich's disease, is another, and so are the various myopathies. By "early" I mean those abiotrophies which begin before the development which coincides with growth is over, and often not many years after birth.

The muscles are not usually considered part of the nervous system although they present a close relation to it in intimate structure and function. We may take the most typical form of pseudo-hypertrophic paralysis as a convenient instance of the heredity of the abiotrophies. The muscular fibres begin to waste during the first seven years of life but the bulk of many of the muscles is actually increased by interstitial overgrowth of fibrous tissue and fat; certain muscles are small and some may seem absent from the first. This disease is due only to heredity, but the heredity is maternal only; it never comes from the father. The tendency to it is thus germinal, a potential defect of development in part of the ovum, that part which will become the muscles. But it is not usually in all the ova; some sons escape. The female children seldom suffer in this typical form, but they inherit the tendency, or some of them do, and their sons are prone to suffer. In the ova from which the daughters develop, the potentiality of the disease is not in the elements that develop into the muscles, but only in that portion of the protoplasm which will become the germinal tissue for another generation. The same facts are true of other early atrophies, in hereditary optic nerve atrophy, &c.; sometimes they are limited to males, but they are only transmitted by females. If the tendency is thus fixed in the germ tissue, and differently fixed, according to the resulting sex, does not the fact make it probable that the sex is also predetermined? Many have held this view and it is not easy to see how otherwise the facts of these diseases can be explained. The disposition to the disease seems seldom to be present in every ovum. Sometimes it apparently is in every male ovum. Every son has died, as in the well-known family described in the "fifties" by Dr. Meryon, but in that one daughter has failed to transmit the disease; another daughter has had two sons and three daughters—both the sons have died from it, all the daughters are free. In an instance which came under my notice long ago four sons died but the fifth escaped and his sons, of course, are free, but the only daughter, herself free, has her only two sons both affected.

We have many similar instances of the disease in two generations. We have known it just long enough—sixty years—to find it in a second generation, but it is curious how seldom we are able to trace the typical disease in preceding generations, although we are not often able to exclude it from lack of knowledge. But I have met with it in the two sons of a lady (the third and sixth of seven sons) whose lineage and that of the mother of Meryon's cases can be obtained from the Peerage. (I cannot mention the names since members of the families are still alive.) The lineage presents a remarkable fact. Both mothers were descended from a certain duchess who was married in 1774, and in the case of each the descent is solely in the female line. The mother of Meryon's cases I will call Lady A and the other Lady B. Lady A was the granddaughter of the said duchess; Lady B is the great-great-granddaughter. There were sons in both lines, but from their ages at death in Lady A's family there can have been no case of the disease. In Lady B's there is only one that suggests its possibility. A son of her maternal grandmother died at 18, but some other cause is intrinsically more probable. We must, I think, regard it as of definite, though unknown, significance that both these maternal producers of the disease had a single ancestor, and, considering the relation of the disease to sex, their descent by the female line cannot be regarded as an accident. I can offer no suggestion of its meaning. But it is remarkable how free from the disease the ancestors of those who produce it generally seem to be. We may note that isolated cases are more frequent than groups, although the groups comprehend a majority of the actual cases. When females suffer males sometimes escape. Only once have I known the disease to occur in the offspring of first-cousins. There resulted four cases of albinism, one of whom had also pseudo-hypertrophic disease. Neither malady had occurred before. But there had been some previous instances of less close intermarriage during the preceding six generations, and, considering the relation of the disease to the ovum, it can hardly be ascribed to the consanguinity of the actual parents. Of the origin of albinism I hope we shall hear more in the course of the discussion.

Other forms of myopathy have been traced through several generations. The facial form of Déjerine and Landouzy has been traced through five generations. This form often does not begin early; its progress may go on through life, and males may transmit it. The first series of Déjerine and Landouzy, just mentioned, bears a distant but interesting resemblance to Mendel's facts. A man and woman married, the woman being atrophic. They had one daughter who was normal, who married a quite healthy man and bore three daughters, all affected. One of these married a healthy man and had two children, a girl, healthy, and a son in whom the atrophy only showed itself at 26, and did not become general until 50. He married a healthy woman and had nine children, six sons and three daughters. A son and daughter died in childhood; of the remaining seven, four were atrophic, two sons and two daughters. If we regard the normal state as dominant and the atrophy as a recessive state, its absence in the second generation, recurrence in the third, and equality in the fourth and fifth are noteworthy features. I have dwelt on these muscular maladies because they present features that are well defined, and because most, if not all, the early nerve abiotrophies agree with them in origin, even in their maternal heredity.

A second class may include the hereditary maladies which begin later in life, after the period of growth is over. They present persistent disturbance of function and are commonly hereditary, but from either side. In the so-called heredo-ataxy of Marie, the symptoms begin about 30 and are usually fatal in about 20 years. It has been found to depend on atrophy of the cerebellum associated with certain tracts of the spinal cord, at least in one case in which three generations were affected. Huntington's chorea begins usually in the senile period of life, but its heredity is well marked and so is that of the peculiar rigidity called Thomsen's disease, a life-long peculiarity of action of the motor nerve structures, also called myotonia congenita.

I must pass some interesting diseases, paralysis agitans, tremors, Graves's disease, &c., in which heredity can be

---

[1] THE LANCET, April 12th, 1902, p. 1003.

In cases which do not respond to medical treatment surgical measures are called for. The operations recommended by authorities are: 1. Laparotomy and free manipulation of the gland. I have shown you this evening a patient who has greatly benefited by this operation. In all probability the favourable results of this operation are attained by the loosening or breaking down of adhesions and consequent relief of tension. In some cases it is possible that the free manipulation of the parts has dislodged a minute calculus obstructing the orifice of the main duct. In most cases, however, a more radical operation is recommended—either (2) cholecystotomy, simple drainage of the gall-bladder, or (3) cholecystenterostomy, permanent drainage of the gall-bladder into the intestines.

The advantage of the simpler operation lies in the fact that it gives an opportunity for the bile to find its way into the intestines by the natural route should the pancreatic swelling eventually subside; cholecystenterostomy, on the other hand, has the advantage of removing the necessity for a second operation should the pancreatic obstruction fail to subside. A large number of cases are now on record where recovery has followed the operation. In some of these cases the condition of the patient at the time of operation has been a very serious one, the state of the gland when seen and handled by the surgeon being clinically indistinguishable from malignant disease, the patient's recovery, however, establishing the diagnosis of chronic pancreatitis. An increasing familiarity with the clinical features of pancreatitis will lead, it is to be hoped, to earlier diagnosis and to successful operative treatment in a class of case which is at present allowed to advance to such an extent as to prejudice the patient's power of recovery. (At the same time I might parenthetically add that a more intimate knowledge of the disease in its earlier phases might lead to the adoption of prophylactic measures which would render the services of the surgeon unnecessary.)

The question of when to operate is essentially one for the surgeon, and on this point I would only refer to two points which have presented themselves to me. The first of these is the inadvisability of delay in cases of chronic jaundice due to the presence of stone in the common bile duct. I have had the opportunity of examining the urine in two cases of jaundice in which the causation was not clear, the diagnosis lying betwixt gall-stones, malignant disease, or chronic pancreatitis. Examination of the urine gave in each instance a negative pancreatic reaction, but prior to the operation, which took place from two to three weeks later, a marked positive reaction was obtained, pointing to extension of the inflammation to the pancreas. At the operation the condition was in each case inflammatory, associated with impacted stone, and extensive adhesions, making the operation a very serious one. In both instances the patients died and it appeared to me that the chances of the patients' recovery may have been lessened by the extension of the inflammation to the pancreas.

The second point has reference to the question of operative treatment in cases unassociated with jaundice, in which the leading features are gastric symptoms, some general constitutional disturbance, a marked pancreatic reaction in the urine with perhaps occasional glycosuria. Mayo Robson and Cammidge have recently spoken strongly in favour of operation in such cases, their recommendations extending to several cases of a genuine diabetic nature. I have no experience enabling me to speak authoritatively on the results of operative treatment in these cases, but it appears to me that great caution is necessary in recommending these cases for operation. Medical measures will in many instances suffice to restore the patients and free them from the subsequent serious risks of diabetes. At the same time we must recognise the importance of early recognition from the surgical standpoint. It seems to me that increased knowledge of pancreatic diseases which must follow the careful study of recent literature of this subject will lead to a better appreciation on the part of practitioners both of the possibilities of medical treatment and of the advantages in suitable cases of early operative interference.

It only remains for me gratefully to acknowledge my indebtedness to my senior colleagues on the staff of the Royal Infirmary for the facilities afforded me in the examination of patients under their charge.

ROYAL SOCIETY OF MEDICINE.[1]

SURGICAL SECTION.

How and Why the Surgeon should Attempt to Preserve the Appendix Vermiformis.

A MEETING of this section was held on Nov. 10th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. C. B. KEETLEY read a paper entitled, "How and Why the Surgeon should Attempt to Preserve the Appendix Vermiformis; Its Value in the Surgical Treatment of Constipation, with a Series of Cases briefly reported." He said that the surgeon should try to preserve the appendix vermiformis. The observations of Macewen had shown that it was not the physiologically useless organ it was supposed to be.[2] It had also a high surgical value as a channel of ingress to, and egress from, the intestine. Suitable cases for this use—viz., for the operation of appendicostomy—were numerous, varied, and frequently occurred in ordinai practice. They might be tabulated as follows: (1) colitis (various kinds; (2) certain forms of intussusception (chiefl to prevent recurrence); (3) intestinal hæmorrhage; (typhoid fever, and certain other cases in which enteriti occurred; (5) cases of enterectomy and colectomy (as safety-valve); (6) intestinal distension in toxic conditions (7) cases requiring the administration of nutrient enemat *per appendicem*; and (8) intractable constipation. In th opinion of Mr. Keetley transplantation of the appendi vermiformis so that the whole or the greater part of i from its root in the cæcum to near its tip lay per manently imbedded in the abdominal wall, would pro duce the good results of excising it and in many case of appendicitis appendix transplantation should be pre ferred to appendicectomy for the following reasons Appendicitis was a dangerous disease, not on account of the nature of the appendix but because of its usual position—i.e., its relation to the peritoneal cavity. Among the cases recounted by Mr. Keetley were some which showed how trivial a malady even perforative appendicitis became when the appendix was imbedded in the anterior wall of the abdomen. Many appendices were in a condition dangerous enough to require operation without the organ itself being as yet seriously damaged—e.g., a fairly healthy appendix containing a large concretion. Concretions, kinks, twists, and strictures could be removed or cured, sometimes with difficulty, sometimes with ease, without removing the appendix. After, however, removing a concretion by what might be termed "appendicotomy," and after undoing a kink, foresight and prudence demanded that the appendix should be transferred from the peritoneal cavity. After removing kinks and twists non-recurrence was insured by transplanting the appendix. The cure of stricture by catheterisation absolutely demanded transplantation in order that the stricture might remain accessible. Examples of all these conditions were given in the cases reported by Mr. Keetley. He also considered that a further reason for preserving the appendix was the possibility of the truth of a part, if not the whole, of Professor Metchnikoff's teaching as to the evil influence of the bacteria of the large intestine in hastening the changes characteristic of old age. Through the appendix vermiformis the large intestine could be regularly washed out from end to end. Some of Mr. Keetley's cases illustrated that practice extended over several years, apparently with great benefit. In conclusion, Mr. Keetley said that appendicostomy was, on the whole, the best and most generally applicable surgical treatment of obstinate constipation because: (1) a long tube could be more easily and thoroughly washed out when open at both ends; (2) an appendicostomy gave direct access to the upper part of the large intestine; (3) medicines administered through it did not disturb the stomach and small intestine, while they reached the cæcum and upper part of the colon better than when given per rectum; (4) appendicostomy and appendix transplantation when we come to compare the differences in the incidence of cancer in the individuals of a species we are not on such certain ground. We know most about cancer in man. The extraordinary frequency of cancer of the skin of the abdomen in Kashmiris as compared with Europeans would at once suggest some racial difference were it not that we know the causative factor in this case to be one of custom. The Kashmiris wear a charcoal oven against the abdominal wall and Europeans do not. Many other instances could be quoted all pointing in the same direction. Taking the surface of the body as an example, the incidence of cancer in different races of mankind is characterised on the whole not so much by innate racial peculiarities as determined by extrinsic irritants. Why some individuals escape the consequences of peculiar practices involving chronic irritation and others do not it is at present impossible to decide. Disregarding all other hypotheses we fall back on an undefined susceptibility of the body which we conceive as being more exaggerated in some persons than in others. There is certainly no evidence for the inheritance of cancer as such, only the possibility of a predisposition can be discussed.

---

[1] A report of the adjourned special meeting of this society which was held on Wednesday afternoon, Nov. 18th, will be found on p. 1544. The reports of the Clinical and Pathological Sections will appear next week.

[2] THE LANCET, Oct. 8th, 1904, p. 995.

To ascertain the part heredity may play in leading up to this predisposition we can resort to statistical or to experimental methods. It is quite possible to discuss the part heredity may play in the incidence of disease without discussing any other causative factor; but in any such attempt the investigator will be biased according as he believes that the particular disease under discussion is purely endogenous or purely exogenous in origin. Now although it would be without the bounds of my subject to make an excursion into the cause or causes of cancer I think it well to preface what I have to say regarding heredity by stating that in recent years a great deal of new evidence has been accumulated in support of the view that a malignant new growth contains nothing foreign to the organism attacked. I may instance two classes of new facts.

I. Carcinoma and sarcoma can be grown continuously only in other individuals of the same species of animal. The continuous growth which follows transplantation can only be prevented by vaccinating with the normal tissues or malignant new growths of the same species, and the degree of protection normal tissues confer is so much the greater the more nearly the tumour transplanted corresponds to the normal tissue used to induce protection. From these observations it is deducible that the malignant new growths of a species retain not only the tissue characters of the species but also the bio-chemical as well as the histological characters of the several tissues of the individual species.

II. Investigations into questions of metabolism—viz., into the relation of a malignant new growth to its host—have shown (*a*) for sporadic tumours in Murray's experiments; (*b*) for Murray's and Haaland's experiments on transplanted tumours; (*c*) for Cramer's and Copeman and Hake's experiments on the gastric secretion in mice affected with spontaneous and transplanted cancer; and (*d*) for Cramer's observations on the gaseous metabolism in rats bearing transplanted sarcoma, that the relations of a malignant new growth to its host are merely those of nutrition—of the demand for, and the supply of, the normal foodstuffs from which tissue is built up, and analogous to those obtaining between fœtus and mother. There is no evidence of pathological products, toxins, ferments, or what not, which *per se* cause ill-health. There is no analogy with any known form of infective disease. This being so, we may seek primarily for the cause of cancer within the body itself in the biological properties of its cells as contrasted with exogenous causes.

The fact that cancer may develop as a response to diverse external agencies, acting as mediate causes, is thereby not excluded, although the ultimate origin of cancer is sought in a biological alteration of what were normal cells. This conception of the origin of cancer seems to indicate that a variable and perhaps inherited predisposition or vulnerability towards excitants is not a possibility to be lightly dismissed. How otherwise are we to explain why one patient responds not at all, another, e.g., with a chronic ulcer, and a third with a malignant new growth at the site of irritation, in which series of events the nature of the irritant appears to be of less moment than the point to which it is applied, and the points of application themselves may be anywhere on the surface of the body? A direct endeavour to ascertain by statistical methods whether heredity selects those who suffer from cancer requires at the outset a clear conception of its distribution among the population as a whole, and of the nature of the evidence which would justify us in deducing that those who suffer from it are afflicted because their ancestors also succumbed to the disease. It is therefore necessary to point out how frequent cancer is as a cause of death, in those members of the community generally, who are above 35 years of age, and because this is so, to anticipate that if heredity play any part it will be a dominant part. On the assumption that an inborn tendency to cancer is transmitted we will expect to find, if we examine a large number of families of which one or more members have suffered from cancer, that the number of cases occurring in them greatly exceeds the average number in the population as a whole, regard being of course paid to distribution for age and sex. On a closer analysis of the family histories of those who suffer from cancer and of those who do not we would expect the population to fall easily and naturally into two groups: (1) in which the disease develops not at all or only as a rare variation; and (2) in which it appears and reappears with constancy in a very high proportion of all the lineal descendants who attain to the "cancer ages." If this easy grouping should not be attainable it will not be permissible to resort to subsidiary assumptions to explain why the disease appears to skip a generation or generations in the direct line of descent, or to make up for the deficiency of the evidence of lineal transmission by bolstering it up with the irrelevant occurrence of cancer in collateral descendants. To be obliged to have recourse to either the one or the other of these supports is tantamount to discarding the thesis that if hereditary then it will be so in proportion to the degree of concentration of the hereditary factor.

The great frequency of cancer is best illustrated by the returns of the Registrar-General which show that in 1906, out of a total of 141,241 deaths of males above 35 years of age 12,695 died from cancer, and out of a total of 140,607 deaths of females over 35 years of age 17,671 died from cancer. Thus, the chance, assuming no more heredity than is shown by an average member of the entire population, that a man over 35 years of age will die from cancer is 1 in 11 and the chance for a woman above the same age is 1 in 8. A calculation based on a similar approximation for 1905 shows how often, taking the proportions as 1 in 12 and 1 in 8, no death, or one, two, three, &c., deaths *from cancer may be expected to be recorded in 100 families*, half the members of which are men and half women, *no hereditary tendency being assumed* beyond what is indicated above and excluding all persons dying under the age of 35.

Number of deaths from cancer in family.	Per 100 families of 6 members, viz., 3 men, 3 women.	Per 100 families of 8 members, viz., 4 men, 4 women.	Per 100 families of 10 members, viz., 5 men, 5 women.
None	51	41	33
One	36	39	39
Two	11	16	20
Three or more ...	2	4	8
	100	100	100

The calculation establishes the fact that when no hereditary influence is assumed the frequency of cancer as a cause of death is so great that few families of large size escape and in one of every two families either a parent or a grandparent will on an average have died from cancer, supposing such parents and grandparents to have died after 35 years of age. Suppose a man and wife both of whom died from cancer 60 years ago; further suppose that of their children, three males and three females, all survived and married and that two of them, one male and one female, married children of parents who died from cancer like their own parents, while the others married into families with no history of cancer. Were it possible to follow the fate of all descendants of these six families the comparative frequency of cancer in those of double cancerous heredity and in those of single cancerous heredity might be expected to show whether a tendency to the disease is transmitted. Were accurate detailed analyses obtainable of the incidence of cancer in a large number of families, and if they showed to a general pyæmia as shown in the last case. These cases, however, seem to show that the organism is generally associated with other organisms such as the pneumococcus. The following post-mortem and bacteriological report was made by Dr. James Ritchie and Dr. Stuart Macdonald :—'Case 2.—There was a purulent subdural meningitis over the left hemisphere, a purulent pia-arachnoiditis in patches over the surface of the brain, and spinal meningitis about the lumbar cord. From the abscess in front of the ankle-joint, the elbow-joints, cerebro-spinal fluid, and peripheral blood a Gram-negative bacillus was obtained in long filamentous forms. It was motile, grew on all media, did not liquefy gelatin, and somewhat resembled the typhoid bacillus in its characters, giving a slight acid reaction in milk and glucose. There was in the case evidence of a terminal pneumococcal infection. The bacillus was pathogenic to monkeys and mice, very slightly to guinea-pigs and apparently to rabbits. It appears to break down the resistance of the animal to other pathogenic organisms. The importance of the case seems to rest in the production of the pyæmic process by a probably hitherto undescribed organism.' Dr. John Thomson and Dr. J. S. Fowler have kindly permitted me to refer to two cases (Cases 3 and 4) under their charge, the bacteriological findings in each case being similar to those above recorded. Without referring at any length to these cases I may say that they presented the symptoms and course of a post-basic meningitis. In Dr. Fowler's case head retraction appeared one week after the onset of the illness, which was ushered in with vomiting. Lumbar puncture on six occasions was performed and indefinite diplococci were found. The child was treated with Flexner's serum but died five weeks after admission to hospital. The bacteriological examination in these cases, carried out by Dr. Stuart Macdonald, gave a similar finding to that described fully in Case 2."—Dr. ALEXANDER BRUCE said that evidently this was a new disease which had to be added to clinical medicine. There was no reason to suppose that the organism was in a temporary stage. It was probable that infection might spread from the abdomen along the line of lymphatics which accompanied the nerves to the spinal cord.—Dr. J. S. FOWLER said that the meningitis differed from ordinary post-basal meningitis by the clonic spasm which it induced.—Dr. GEORGE ROBERTSON alluded to a branching streptothrix which he had observed in a case which was under his care and which exhibited many of the symptoms of general paralysis.—Dr. CHALMERS WATSON read a paper on the Diagnosis and Treatment of Pancreatic Disease. (The paper appears *in extenso* at p. 1519 of our present issue.)—Dr. J. O. AFFLECK said that there was a great difficulty in diagnosing diseases of the pancreas from diseases of the liver and many cases of supposed pancreatic disease had been shown by post-mortem examination to have been hepatic. Cammidge's test was one not easily applied by the general practitioner and Dr. Watson seemed to rely greatly on this test as a means of diagnosing pancreatic disease. Whether it could be taken as an absolute test of disease of this organ was very much open to question, as the test might give a reaction in other diseases. He thought that a good deal more research was required before one could arrive at an easy diagnosis of pancreatic disease. He desired to emphasise the grave responsibility the physician incurred in recommending exploratory operations which were not without risk. Dr. Affleck did not suppose that many, if indeed any, physicians in Edinburgh had had more of these operations performed for patients, and it was not without reason that he regarded the physician's part as a very important and a very serious one.—Dr. WILLIAM RUSSELL agreed with Dr. Affleck that the value of the communication lay in the large number of observations carried out with Cammidge's test. The subject of pancreatic disease was a very wide one and for the present the severe affections such as acute pancreatitis might be set aside. During the past 20 years or more there had been two periods when diseases of the pancreas were boomed. During the first, "pancreatic dyspepsia" was the fashionable diagnosis; during the second it was "amylaceous dyspepsia," and many people had it. It had to be remembered that the pancreatic juice was the most important of the digestive fluids, for it contained three powerful ferments. The pancreas was quite different from the liver, the one being a secretory, the other an excretory gland. Primary disorders of the pancreas with an anatomical basis were rare and the clinician was not entitled to assume the existence of conditions that those who had looked into the matter did not recognise. On the other hand, every chemical pathologist knew how the pancreatic secretion could be secondarily affected. Cammidge's test if it meant anything implied that pancreatic secretion was absorbed and excreted by the kidney. It was well known that in duodenitis, in gastro-enteritis, and in simple enteritis the catarrh affected the flow of the pancreatic juice and therefore influenced the whole process of digestion. A duodenal catarrh was sufficient to account for catarrhal jaundice and for the interference with the pancreatic flow which would lead to a positive urine reaction under such conditions. In some of the classes of cases referred to in the paper the differential diagnosis could be made without this test, and indeed the test could not possibly be of assistance in many cases where a differential diagnosis was of great importance. He thought Dr. Watson placed too high a value on the test, but the paper would lead him (Dr. Russell) to go into the subject again although he had tried it early and discarded it.—Mr. C. W. CATHCART, Mr. CARMICHAEL, and Dr. FRANCIS D. BOYD took part in the discussion.—In his reply Dr. CHALMERS WATSON said that the physiology of the test was as yet not known. The actual performance of the test was not easy and he had himself failed in trying it until he had had a practical lesson by the inventor. He said that the test was not pathognomonic of pancreatic disease. He believed that pancreatic disturbances were much more widespread than was supposed, and this his observations had proved. In the majority of cases this test was not essential in the diagnosis of pancreatic disease, but it ought to be taken in conjunction with other methods of investigation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Presidential Address.—Exhibition of Cases.

A MEETING of this section was held on Oct. 30th, the PRESIDENT, Mr. JOHN LENTAIGNE, being in the chair.

The PRESIDENT, in opening this the twenty-sixth session of the Surgical Section of the Royal Academy of Medicine in Ireland, said he had come to the conclusion that the most appropriate subject with which he could deal was the present condition and future prospects of the Academy. He could remember the wave of enthusiasm that spread over the profession 25 years ago when the Academy was founded by the amalgamation of the existing medical, surgical, and pathological societies. The zeal and enthusiasm that were excited produced rapid and remarkable effects in crowded meetings and papers so numerous that many could not be read. He could remember also how the wave of enthusiasm abated and how apathy and loss of interest grew until now the society had, in his opinion, reached the lowest possible ebb; and the prospects of the future were of the very worst. Unless a very great change took place decay and dissolution were inevitable. He had no desire to bolster up an effete or useless institution and if the Academy was of no value to science in Dublin then the sooner it was decently buried the better. He, however, asserted most emphatically that the Royal Academy of Medicine was a necessary and valuable asset to the scientific life of Dublin and it would be their own fault if they allowed it to dwindle into worthlessness as compared with similar institutions in London, Paris, and Vienna, or even in the smaller continental cities, such as Lyons, where societies like theirs were doing work of the most valuable kind for the entire world. In Dublin there were plenty of material, plenty of brains, and plenty of most excellent work being done, and they must make an effort to prevent its being wasted to the world as well as to the individuals themselves. He had summed up the causes of decay under three heads. The first was the apathy of the senior members of the profession. Allowance had, of course, to be made for overworked medical men advancing in years who had difficulty in coming out in the evening to hear papers on matters which they might possibly think of very little use to them. Still he thought public spirit should induce a man to support an institution that had once been of use to him, and there were very few senior members of the Academy who had not gained from it. There was no man those family histories with an exceptionally high incidence of cancer, or where, as pointed out by Butlin, the disease appears only on one side of the family, as if introduced by some grandparent or parent; e.g., such family histories as the following, kindly supplied to me by Mr. Edward Jessop, are certainly very suggestive, but unfortunately the information as to ascendants and collaterals gives out just where it would prove of value. A man, one of a family of nine, died from cancer of the liver, the others being all alive and well. The patient's mother was one of a family of 13, seven of whom (four males and three females) died from cancer. Two died from cancer of the bladder, two from cancer of the liver, and one each from cancer of the throat, uterus, and breast. In another family of nine children five died from cancer (four males and one female). The four males all died from abdominal growths (cæcum). The female died from cancer of the uterus. The mother and the mother's brother also died from cancer. The father died from phthisis. The son of the eighth son recently died from cancer of the bowel at the age of 23 years.

Family histories of this kind are, however, rare in proportion to the number of individuals attacked and they are mainly of interest as showing that if cancer be transmissible by heredity then transmission takes place both through the male and the female without anything corresponding to what is known for hæmophilia and colour blindness. These histories are so infrequent that they cause no surprise when the table of the relative frequency of cancer in the general population referred to above is considered, for did these forms of family history imply hereditary transmission then we should be able with ease to obtain tables of 100 families in which the figures for no deaths, one, two, three, or more were the inverse of what they are in the population, but this is not the case. The isolated instances recorded in the literature serve only to show how rare this phenomenon really is. When recorded it is more than probably to be looked upon as what would be expected to happen in the case of so frequent a cause of death as cancer, from a consideration of the distribution theoretically calculated according to the law of probabilities. To sum up the inferences which may be drawn from the crude statistical data in man there is nothing which one would be justified in submitting to the biometrician for nearer analysis. There is, in short, no evidence of cancer arising as a transmissible variation. It seems, then, that cancer is probably always acquired.

Turning to the experimental investigation of cancer in animals, alleged epidemics have often been recorded in them, especially for mice and rats housed together in small cages. Satisfactory proof that these aggregations of cases were due to infection has not been furnished and the alternative explanation that they arise as the result of in-breeding cancerous stock has naturally suggested itself. Our very detailed observations on many ten thousands of mice have not revealed in our laboratory anything which we would call an epidemic. When, however, we take into consideration the manner in which cases of carcinoma mammæ have been sent to us by breeders, we find the same kind of evidence as that which has led observers in France, America, and Germany to assert that epidemics of cancer occur in breeding establishments. We may illustrate this kind of evidence by the numbers of tumour mice sent in by four of the breeders who supply us with mice under a guarantee that no fresh stock has been introduced. From Jan. 1st, 1906, to Oct. 31st, 1907, Mr. A. sent us 10 cases, Mr. B. 6 cases, Mr. C. 35 cases, and Mr. D. 18 cases of carcinoma of the mamma. These figures, which are more remarkable than any others yet published, are no evidence that there was an endemic or epidemic occurrence of cancer in the breeding cages of Mr. C. or Mr. D. The proportion of mice supplied to us in the same period to cases of cancer were as follows:—

	A.	B.	C.	D.
Tumour mice	10	6	35	18
Total mice	1302;	1547;	9653;	11,842.

The number of tumours occurring in these stocks of mice has been determined solely by the number of mice of "cancer-age" under observation. This is brought out particularly clearly in the difference between the age constitution of the stock of Mr. C. and Mr. D., since the stock of the latter contains constantly a much higher proportion of young animals, and he supplies us with most of our young mice. Further, if we note the dates on which tumours are sent to us and arrange them in columns we find that the crops of tumours coincide with the aging of groups of mice. Thus those apparent aggregations of cases, wrongly called epidemics by too enthusiastic advocates of a parasitic origin for cancer, also give no indication of haphazard in-breeding leading to a preponderance of cases of cancer of the mamma. The incidence of the disease for mice continues to obey the laws of age and sex distribution even where in-breeding is proceeding haphazard.

We have therefore devoted great attention to systematic breeding experiments, of which the starting-point has been not merely mice of so-called cancerous stock but mice which had also *actually suffered* from cancer. Thus the objection has been met of those who might argue that unless the disease had been present in the parent there was no opportunity for its transmission. The question of heredity of cancer of the mamma, or of a predisposition to it, is now in a fair way to final settlement. The mouse has the great advantage that its life is short, and many successive generations can be accurately observed and age, dates of birth and death, parentage, cause of death, and post-mortem examination fully recorded. In addition a comparison with an average sample of the mouse population is possible. The surgical removal of spontaneously occurring mammary tumours of which the clinical course and the pathological examination leave no doubt whatsoever that the tumours were malignant epithelial new growths, has enabled us to prolong the life of many mice and to breed from them. Breeding from such elderly mice is not an easy matter and much patience has been necessary. By successively crossing other spontaneously affected animals with the offspring of cancerous parents, strains are being obtained in which the cancerous heredity is ½, ¾, or 15/16, and even higher. The concentration of a hypothetical hereditary factor in a *known* amount and in large numbers of animals of *known* age should in the course of a few more years definitely settle whether there is a family or only an individual liability to the disease. As yet we have obtained only a few cases of carcinoma of the mamma and no cases in other organs. Thus far there is no evidence that the liability to carcinoma has been enhanced by systematic in-breeding. I do not wish to anticipate the results of our observations, which are still continuing, but we have not as yet obtained even an indication that cancer is inherited. It appears to be very doubtful whether there is transmitted even a power of acquiring the cancerous modification under excitation; and it is not impossible that cancer may be really a late modification of healthy tissue acquired *de novo* for each individual and in which the bogey of inherited predisposition—the dying echo of ancient constitutional conceptions of cancer as a blood disease—plays no part whatsoever.

The question will be asked: If experiment does not as yet support the conception of an inherited predisposition, why does cancer arise in one individual and not in another who has been subject to the same irritant on the same region of the body? One of the most important results of experiment has been the absolute demonstration of the truth of the belief to which I suppose we all subscribe nowadays, that cancer is primarily circumscribed. The fact that occasionally there may be more than one primary focus in the same individual or that a single focus may comprise a number of centres does not fundamentally affect this view. Another important result of experiment has been the demonstration that the conditions of origin are fundamentally distinct from the conditions of mere growth into a tumour, and a third the proof that the soil provided by a mouse or a rat can be experimentally modified in two directions. It can be rendered absolutely unsuitable or more than normally suitable for the growth of transplantable carcinomata and sarcomata. It has been amply shown that the tame mice of England differ in their susceptibility to transplantation from those of France, Germany, or Denmark, and that German mice may be modified—e.g., by prolonged sojourn in Norway, and English mice by prolonged sojourn in Germany. Another form of constitutional influence which is of moment, at any rate in the case of some transplantable tumours, is that the presence of a primary tumour can effect a secondary modification favourable to dissemination and metastasis formation. Observations have also been recorded, but are as yet unconfirmed, that the histological structure of a tumour can be modified by the influence of the "soil."

of the infection of the arm the uterus remained unaffected. —The PRESIDENT said it was a most remarkable case because of the absence of uterine sepsis with the terrible infection in the upper limb, and because of the exceptional success of the result.—Mr. WHEELER said that he had a similar case in which tetanus supervened but the patient recovered. Where tetanus was likely, he thought the antitoxin should be given the whole way through, but the PRESIDENT said he had lost faith in antitetanic serum.—Mr. KENNEDY, Mr. HAUGHTON, and Mr. W. TAYLOR also spoke.—Mr. STOKER, in reply, said he had taken the line that when the woman was not losing any ground it would be better to delay the amputation a few days from the confinement, as she had been working hard and had not been well fed.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 6th, Dr. T. K. Monro, Vice-President, being in the chair.—Dr. A. G. Hay showed a case of Traumatic Paralysis of both Suprascapular Nerves caused by falling on the palms of the hands with the arms extended forwards. The supra- and infraspinati were atrophied and the shoulder-joints were painful; the arms could not be raised above the shoulder level or pressed firmly against the sides. The affected muscles reacted sluggishly to faradic and normally to galvanic stimulation. There were no sensory changes.—Dr. W. K. Hunter showed: 1. A case of Pure Motor Aphasia in a healthy man, aged 62 years. The condition came on suddenly at night. Four years before he fell down in the street and remained unconscious for half an hour but was able to walk home shortly afterwards. Six months ago he suffered from "cardiac spasms" but nothing abnormal was made out from examination of the heart. He had a facial paralysis lasting for from 24 to 48 hours but his inability to speak had remained absolute for three weeks. He could only say "yes" and "no," and "John." He tried to say the days of the week and made seven separate sounds which had a certain rhythm resembling the words. He could write well and understood everything said to him. His mental condition was quite acute. The condition seemed most likely to be due to a thrombosis. There was no cardiac condition to account for embolism and the blood pressure was too low to suggest hæmorrhage (105–120). 2. A case of Little's Disease in a child, aged three and a half years. There was a history of a difficult labour and artificial respiration had to be performed for half an hour. He had not learned to walk or to talk, though he seemed to understand what was said to him. There was no rigidity about the muscles.—Dr. R. Barclay Ness described: 1. A Fatal Case of Hodgkin's Disease in a man, aged 41 years. In childhood he had tuberculous cervical glands, and when aged 29 years the glands in the right axilla became enlarged and six years later those of the right side of the neck. A few months ago the glands of the left side of the neck and axilla and of the right groin rapidly became enlarged. There was some œdema of the right side of the thorax. Cachexia was marked, but there was no bronzing or jaundice. The spleen was considerably enlarged. Dyspnœa was marked and there were left-sided pleural effusion and ascites. Dr. John H. Teacher in a pathological report said that on section the appearances presented suggested a tumour rather than Hodgkin's disease. The glandular enlargements were quite characteristic of the latter, but the involvement of the liver and spleen took the form of a few large, rounded masses exactly resembling secondary carcinomatous tumours. There was, moreover, perforation of the trachea and œsophagus by the new formation and there were numerous small superficial growths on the peritoneum which were very suggestive of metastatic growths due to invasion of the cavity. The histological characters of all the growths were those of lymphoma or Hodgkin's disease. There had been a very old tuberculous infection of the lymphatic system and lungs which was represented by numerous calcareous masses. There was no recent tubercle. Tubercle bacilli could not be found. 2. A case of Carcinoma of the Stomach in a boy, aged 14¾ years. There was a history of abdominal pain for two years and of jaundice of two months' duration, also of a small umbilical tumour of three to four months' duration. Hæmatemesis was present on two occasions; melæna on one occasion. There were considerable tympanitic distension and tenderness. The abdomen was opened by Dr. Alexander MacLennan, fluid drained off, and an anastomosis made between the distended gall-bladder and jejunum. The nature of the case was made out after examination of the tumour mass removed. Dr. Teacher in a pathological report said that the primary lesion in this case was an ulcer, very like a simple chronic ulcer of the stomach, but with unusually thick edges and much diffuse thickening around it, situated on the lesser curvature about two inches from the pylorus. The thickening extended fully an inch from the edge of the ulcer, so that there was a clear strip of stomach between it and the pyloric ring. There was very widespread lymphatic dissemination involving the adjacent lymphatic glands, the gall-bladder and common bile duct, and the omentum and mesentery. The two last-mentioned structures were studded with small nodules. Microscopically the tumour was a very hard scirrhus carcinoma. The epithelial processes were very fine and had disappeared almost entirely from much of the tumour. A few traces of glandular structure persisted, showing clearly its gastric origin. It appeared probable that it developed upon a chronic gastric ulcer.—Dr. J. S. McKendrick reported a case of possible incipient Addison's Disease. The chief features of the case were: pigmentation of the skin with patches of white, consolidation of the left apex, expectoration with tubercle bacilli, anæmia, and enlarged spleen. The blood count was normal. Dr. McKendrick discussed the question whether this was a case of disease of the suprarenal capsules with secondary involvement of the lung and splenic anæmia or whether it was a case of Addisonism. The patchy nature of the pigmentation appeared to resemble that in cases recorded of leucodermia associated with Addison's disease.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Nov. 4th, Dr. A. T. Wilkinson, the President, being in the chair.—Mr. Garnett Wright described two cases of Traumatic Rupture of the Spleen. The first case was that of a woman, aged 35 years, who sustained a rupture of the spleen as a result of a kick in the abdomen. Slow hæmorrhage occurred and operation was performed 48 hours after the injury, the hæmorrhage being controlled by gauze tampons. The patient recovered. The second case was that of a child, aged two and a half years, who was run over and presented signs of internal hæmorrhage. Operation revealed a tear right through the spleen. Splenectomy was performed but the child died 10 hours later. Mr. Wright advocated a vertical incision through the right upper rectus muscle with a second incision running transversely to the left from this. In this way not only was good access to the spleen obtained but other organs could be examined. Tamponade was advocated in selected cases and splenectomy advised in the more severe injuries.—Dr. Charles H. Melland read a paper on the Diagnosis and Treatment of Severe Anæmia, with special reference to the differential diagnosis and treatment of pernicious anæmia. He drew attention to the main features of difference between pernicious anæmia and other severe anæmias of secondary origin, laying particular stress upon the difference in the character of the blood, and illustrating them by means of a number of microphotographs of blood films. He referred to the various underlying causes of severe anæmia and to the importance of making use of every method of physical examination in order to arrive at the cause of the disease, and the danger of relying upon the blood examination alone, since rational treatment could only be carried out if the cause had been sought for and discovered. He regarded the common view as to the prognosis of pernicious anæmia as much too pessimistic and liable to paralyse one's attempts at treatment. There was none, in fact, of the more serious diseases which responded more satisfactorily to prompt and efficient treatment. If recognised early some cases might be actually cured, whilst others might have several years of fairly comfortable life insured to them. He showed microphotographs of the blood from cases which had been greatly ameliorated or cured. Arsenic was still the most useful drug but it was useless unless given in increasing doses and its effect must be watched and guarded by periodic blood examinations. Oro-gastro-intestinal antisepsis was of almost equal importance, and, like the arsenic, must be kept on in a minor degree long after apparent recovery, the dose being increased if the blood examination showed any tendency to relapse. He had found raw red-bone-marrow effective as an adjuvant in some cases that were proving refractory to the other influence of environment may be brought forward to show that such statistics are probably misleading.

1. The statistics are nearly all based on comparatively small figures. It is probably owing to this fact that the estimates given by different authors vary greatly. Thus the estimates of the number of persons who have a hereditary predisposition to tuberculosis are variously given as being from 10 per cent. to 80 per cent. of the general community.

2. The statistics are based on answers obtained from individuals as to the cause of death or the occurrence of tuberculosis in their ancestors and relatives. In most investigations the answers given by uneducated people are accepted with little reserve. Hospital experience has shown us that such data are quite unreliable in the lower middle and poorer classes. An insurance experience which brings nearly 4000 family histories annually before my notice has convinced me that even intelligent members of the upper classes are strangely ignorant of the disease history of their families and that their statements as to the cause of death are frequently unsubstantiated by further investigation. Most medical men will agree with me when I suggest that statistics as to the incidence of tuberculosis which are based on the statements of relatives are absolutely unreliable.

3. Most of the family histories collected on this hearsay evidence are incomplete. In nearly all investigations children or others whose life-history is not at an end are included. In view of the fact that there is good clinical evidence to suggest that infection may occur and yet not give rise to the clinical symptoms of the disease for some years, it is clear that if we are to have a complete picture we must have completed family histories.

4. The statistics are all confined to the influence of one example of tuberculosis—namely, the pulmonary form—and in most instances all reference to the occurrence of tuberculosis of the glands, bones, joints, testicles, peritoneum, &c., is omitted. Recent research has shown that the organ or tissue which may happen to be infected is largely a matter of chance, which is determined chiefly by the portal of infection and partly by the age of the affected person. The differences due to the age of the affected person would appear to be dependent in part upon the distribution and arrangement of the lymphatic system at various periods of life. The transmission of any defective resistance to tuberculosis is probably independent of the fact whether we are dealing with pulmonary or bone tuberculosis, for it is no uncommon thing to find three or four different forms of tuberculosis in one and the same family. It has become clear that if we are to have clean evidence on the subject of the transmission of a hereditary predisposition in this disease, we must not confine our attention to examples of pulmonary tuberculosis but must embrace all forms of tuberculosis in our inquiries, more especially when we remember that all the various forms are capable of producing, and eventually often do produce, the pulmonary form in their host.

5. The statistical investigations are confined to tuberculosis which has been associated with definite clinical signs, and no differentiation has been made between persons who have become cured, and have therefore acquired a partial immunity, and those who have been unable to make any effective resistance to the disease. Further, all reference has been omitted to cases of pulmonary tuberculosis which have become spontaneously healed (cases, that is, in which a partial immunity has been acquired) without showing any evidence of the disease during life. How frequently tuberculosis undergoes a spontaneous cure, and in a large proportion of cases without ever having been detected during life, is shown by pathological records. It is generally allowed that there is evidence at death of tuberculosis having occurred in at least from 30 to 50 per cent. of the community, and that the proportion increases with age, that is as the risks of infection increase. Some authors go further and many of us will be inclined to agree with them; thus Naegeli found evidence of tuberculosis in 97 per cent. of 500 consecutive necropsies, and Osler has stated that if a systematic laboratory investigation is made tuberculous lesions are found practically in 100 per cent. of adult bodies. It is highly probable that persons who have acquired a partial immunity and have overcome the infection, and persons who are unable to acquire any real immunity or to offer real resistance to the disease have different effects on their descendants. It is possible that the one might represent the long plants investigated by Mendel and the other the short plants. No allowance for this possibility has been made in any investigation I have read.

It is clear to my mind that statistics which are based largely on old wives' recollections, on uncompleted family records, on a selected form of the disease, and in which no reference is made to the fact whether any immunity has been acquired or not, cannot give us a scientific insight into the question of a hereditary predisposition. It is also clear that any statistical investigation, if it is to be scientific and not futile, must be based on adequate post-mortem records of the grandparents, parents, and every member of the family.

If we consider these statistics which are based on family histories, and to the value of which I have brought forward the above objections, what do we find? Dr. F. C. Shrubsall, who has investigated the records of the Brompton Hospital, will tell you that it is difficult to arrive at any definite conclusions. Professor Karl Pearson's investigation, which is perhaps the most recent and careful one, but which has many of the faults to which I have alluded, is based on between 200 and 300 "fairly complete" family histories. Professor Pearson holds that his figures show that 50 per cent. of the offspring of tuberculous parents become affected with tuberculosis and adds that he is inclined to think that the theory of infection does not account for the facts and that the constitution or diathesis means almost everything for the individual whose life cannot be spent in self-protection. If we allow that 50 per cent. of the offspring of those suffering from pulmonary tuberculosis eventually suffer from this form of the disease owing to their inherited want of resistance, we should, I think, expect a progressive increase in the incidence of the disease and a progressive increase in the mortality. Now what do we find? Pathological evidence shows that most of us have tuberculosis at some time, but that most of us have sufficient resistance power to overcome the infection. In spite of the fact that all of us are infected, the statistics of this country show that each decade we are more able to resist the disease. The Registrar-General's statistics show that the total annual deaths from pulmonary consumption have fallen from 59,035 in 1838 to 39,746 in 1906, in spite of the enormous increase of the population during that period, and the death-rate per 10,000 living has been reduced during that period from 38·9 to 11·5. The factors of immigration and emigration cannot have affected these figures, for tuberculosis is an almost universal disease and the incidence in England and Wales is less than that of most countries. It might be that this enormous decline depended on the comparatively early death-rate of consumptives and their lessened capacity for producing children, but we find that from 1851-60 to the present time the age of maximum mortality from pulmonary tuberculosis has risen in males from between 20 and 25 to between 45 and 55 and in females from between 25 and 35 to between 35 and 45, and that therefore the capacity for consumptives to produce families and to transmit the predisposition, if it exists, has been very largely increased.

It is difficult to correlate these facts which are based on large and probably fairly correct figures with the assumption that an inherited predisposition to consumption is transmitted from one generation to another. They certainly suggest that further investigation of a more scientific kind is required before we can usefully draw conclusions from the statistical investigations which purport to show that there is an inherited predisposition to this disease. It is difficult to account for the progressive fall in the incidence of consumption. Still, it is worth while to make the attempt. The chart exhibited (taken from Dr. H. T. Bulstrode's report on sanatoriums) shows that the fall has been gradual and continuous. It further shows that such things as the Public Health Act of 1875, the discovery of the tubercle bacillus, the Housing of the Working Classes Act, and the commencement of notification and sanatorium treatment have produced no immediate or unusual fall. There can be no doubt that during this period preventive measures, which I have already shown can definitely affect the mortality from the disease, have had their effect. The limitation of the opportunities for repeated infection, perhaps more especially by segregation to which Dr. A. Newsholme has drawn attention, must be credited with some part of this improvement. The better splenic puncture and Colonel W. B. Leishman, R.A.M.C., had succeeded in obtaining developmental forms by cultivation in Novy medium. Photographs illustrating the parasites as recovered from the spleen and the developmental forms obtained were shown. Treatment had consisted of soamin (gr. 3) by intramuscular injections, x ray exposure to the spleen, and hetol by intravenous injection. On the whole, the patient had improved somewhat, especially as regards his blood condition and temperature.—Captain J. C. Kennedy, R.A.M.C., showed two patients. The first was probably a case of functional paraplegia, but in the early stage of the disease it was thought that the man was suffering from locomotor ataxia and the diagnosis was still to some extent open. The second was a case of paralysis of the oculo-motor nerve in which the diagnosis lay between the ophthalmoplegic migraine of Charcot and a neuritis of rheumatic or influenzal origin. Captain Kennedy pointed out that the possibility of the existence of a nuclear paralysis should not be overlooked. —Major H. W. Grattan, R.A.M.C., showed photographs of a case of Elephantiasis.—Fleet-Surgeon P. W. Bassett-Smith, R.N., contributed two pathological specimens: (1) Aneurysm of the Heart; and (2) Diaphragmatic Hernia. There was a large rent in the diaphragm through which the spleen and portions of the stomach and transverse colon had been forced.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 5th, Mr. R. F. Jowers, the President, being in the chair.—Mr. A. H. Tubby read a paper entitled "Arthritis Deformans (Rheumatoid Arthritis), with a Notice of Recent Surgical Treatment." He divided arthritis deformans into three groups: 1. Still's disease, which occurred in children before the second dentition, and was characterised by swelling of the joints, enlargement of the lymphatic glands and spleen, and arrest of bodily development. As treatment he advised arsenic and good food. 2. Rheumatoid arthritis, occurring mainly in females between 15 and 30 years of age and at the climacteric, usually subacute. It began by hypertrophy of the synovial membranes, while the ends of the bones became atrophic and transparent to x rays. It was a disease of debility and might be due to septic absorption from the uterus, carious teeth, a rectal ulcer, or auto-toxæmia from the intestine. Any possible septic focus should be treated surgically, and any joint which was much swollen or very painful should be opened and washed out and any excrescences of synovial membrane removed. He strongly recommended lactic acid milk diet to combat auto-toxæmia, guaiacol, arsenic, and iron as medicines, and locally radiant heat. 3. Hypertrophic or osteo-arthritis, a disease of the latter half of life, beginning in the bones, which became eburnised and sclerotic, bony spurs and Heberden's nodes forming, while the synovial fluid was decreased and the cartilages eroded. Removal of excess bone would sometimes help these cases.—The paper, which will be published in an early issue of THE LANCET, was discussed by the President, Dr. Walter Broadbent, Dr. E. Hobhouse, Dr. D. G. Hall, and Mr. G. Morgan.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 12th, Mr. G. B. Mower White, the President, being in the chair.—The President, in proposing that a letter of condolence should be sent to the family of the late Dr. James Grey Glover, spoke of the long association which Dr. Glover had had with the society and of the valuable services which he had rendered to it. One of the oldest members of the society, Dr. Glover had twice held the position of President. On the death of Dr. Syers at the beginning of the session 1906–07 the chair, to which he had been elected, became vacant, and Dr. Glover, with his accustomed unselfishness and at considerable personal inconvenience on account of his advancing years, very kindly stepped into the breach. All who heard the presidential address which he delivered at the close of the session on "The Outlook of the Medical Profession—Scientific, Social, Political, and Financial" will remember with pleasure the lofty ideals which actuated him and the hopeful view with which he regarded the future of the profession to which he was devoted. In conclusion, Mr. Mower White considered that Sir John Tweedy, in his "impressions of Dr. Glover"[1] had ably summed up his character when he said of his life work that it was the outcome of a fine and cultivated intellect, a just, generous, and religious spirit.—In seconding the motion, Dr. Alexander Morison spoke of his long and intimate acquaintance with Dr. Glover, and in a few touching sentences referred to his devotion to his work and to his kindly and generous disposition.—Dr. Morison then showed a case of Cerebro-spinal Meningitis in a child, aged five years, in whom marked improvement had followed the performance of lumbar puncture coupled with the injection of vaccine. He referred particularly to the good effect of drainage in these cases, where the symptoms are due to the intraventricular pressure. The child, who had been admitted to the hospital on Oct. 8th, was now practically well and was about to be sent home. Dr. Morison also showed a case of Heart Disease in a boy, in whom pain of a distressing and anginoid character was relieved by the performance of thoracostomy.—Dr. James Crabb showed a case of Developmental Imbecility in a boy, aged 13 years, in whom there were atrophy and defective movements of the tongue, due probably to a nuclear lesion in the medulla.—The President showed a specimen of an Abnormal Kidney removed by the abdominal route, and a case of Hallux Valgus cured by operation.—Dr. A. H. Pirie showed two cases, one of Idiopathic Keloid and the other a Lymphadenoma, which were undergoing successful treatment by the x rays.—Dr. T. J. T. McHattie showed a specimen of a Complete Gestation Sac delivered at the twenty eighth week, in which the placenta from its wide extent had become prævia.—Dr. Shaw showed microscopical slides of the Meningococcus and the Influenza Bacillus, and also Two Brains from cases of Meningitis.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 11th.—Dr. P. Boobbyer, the President, gave his introductory address on the Birth- and Death-rates of Nottingham during the Past 25 Years as compared with Other Towns. Taking the birth-rate first this showed a fall of 30 per cent. in the last 25 years; indeed, a decrease of some sort was to be found in almost all the civilised cities of the world with certain exceptions, such as those of Ireland, Spain, and parts of Austria and Russia. The probable explanation of the exception in these cases was the local maintenance of the old-fashioned religious beliefs regarding the subject of marriage and its objects. Writers were not wanting to point to the probable outcome of this tendency which was in the direction of the extinction of the families of the ruling and professional classes in favour of a reckless and thriftless proletariat. Turning to death-rates, in the matter of both the general death-rate from all causes and that from the principal epidemic diseases, Nottingham showed a pretty steady improvement like most other large towns, but after making due allowance for exceptional epidemics of measles, whooping-cough, and diarrhœa it seemed clear that progress in the right direction had latterly not been quite so rapid here as in the case of some other similar towns. This was especially true of the death-rate from enteric fever, in which other towns by radical reforms in the matter of scavenging or refuse and sewage disposal had out-distanced Nottingham. During the year 1907, as the result of severe epidemics of measles, whooping-cough, and autumnal diarrhœa all occurring in the same year, the infant mortality for Nottingham had headed that of all other big towns. Pointing out that the local death-rate from pulmonary tuberculosis was actually less than that for London, the speaker, as the result of 24 years of public health work in the county and city of Nottingham, drew the moral that further defects of sanitation would have to be faced and made good, instancing more particularly the demolition or improvement of slum areas, as well as the substitution of a water-carriage system for the present system of dry pail-closets.

LIVERPOOL MEDICAL INSTITUTION.—A pathological meeting of this society was held on Nov. 12th, Mr. T. H. Bickerton, the President, being in the chair.—Dr. W. B. Warrington showed a series of specimens illustrating the relation of different clinical signs, especially ascites, to various lesions of the liver.—Mr. Murray exhibited Typhoid Organisms recently isolated from the medulla of the femur of a patient who had suffered from trouble in this bone since an attack of typhoid fever 29½ years ago.—Mr. W. Thelwall Thomas for example, leads to dental caries; dental caries in its turn leads to oral sepsis. The deposition of tartar from the saliva gives rise to another circle by irritating the gum and causing it to recede from the tooth, leaving the neck and fang exposed. The exposed fang in its turn receives a coating of tartar, exciting further irritation and recession, and so the morbid process is continued, often to be only interrupted by the loss of the tooth. But oral sepsis has constitutional as well as local effects and frequently leads to gastro-intestinal catarrh and malnutrition. "Then a 'vicious circle' may become established; oral sepsis leading to systemic disturbance will tend to lower the resistance locally and to encourage the continuance of infection and absorption."[3] During infancy, while the eruption of the teeth is taking place, sepsis and defective nutrition may complicate the course of events by hindering the proper development of the maxillæ. Such imperfect development promotes dental caries and malnutrition. In the words of Goadby:[4] "Among children we find impaired nutrition and with it impaired growth; with this, again, badly developed maxillæ, and thus the vicious circle is complete."

---

[1] THE LANCET, Oct. 24th, 1908, p. 1255.

GROUP II.—*Circles Associated with the Stomach.*

These may either concern the internal relations of the stomach or its relations with other organs. An example of the first occurs in atonic dyspepsia such as is associated with anæmia. The defective quality of the blood supplied to the stomach in anæmia leads to enfeebled peristaltic movements and hence to impaired nutrition of the stomach. From impaired nutrition results further weakening of the musculature, and thus is established one of the vicious circles so frequently associated with dyspepsia. But a weakened peristalsis has ill-effects extending in other directions. The adequate secretion of gastric juice depends largely on the peristaltic movements bringing the food pulp into repeated contact with every portion of the gastric mucosa. Hence any condition that weakens peristalsis diminishes gastric secretion. The result is that the ingesta are imperfectly digested, remain too long in the stomach, and set up irritation and congestion which further enfeeble the musculature.

Again, the weakened peristalsis which checked the adequate supply of blood and of gastric juice hinders absorption from the walls of the stomach, since such absorption is regulated by the movements of the stomach and by the activity of digestion. If the peptones are not removed at the proper time the necessary repose of the gastric glands is curtailed and digestion of the following meal is hindered. In brief, peristalsis, nutrition, secretion, and absorption are in such close reciprocal relation to each other that disorder in the one invariably involves the others. It matters little which function is first disturbed, the chains of a vicious circle are inevitably riveted round the dyspeptic. In atonic dyspepsia the food is often unduly retained, undergoes fermentation, and causes such an accumulation of gas that the stomach yields to the pressure and dilates. The dilatation in its turn increases the stasis and thus becomes progressive. "This *circulus vitiosus*," as Cohnheim[5] points out, "is aggravated by the fact that the products of the abnormal fermentations may act as exciters of inflammation in the stomach itself and may set up gastritis or add to its severity if already present. It need excite no surprise then that such conditions are, as a rule, very obstinate and are hardly ever perfectly recovered from except after the adoption of a really rational line of treatment." In many of these cases boulimia is a troublesome complication, resulting from, as well as aggravating, the gastric dilatation. Here also "a vicious circle is established and the morbid condition aggravates itself automatically."[6] Occasionally a mechanical condition contributes to the gastrectasis. The enlarged and loaded stomach sinks in the abdomen and pulls down the horizontal section of the duodenum. The result is a kinking of the latter which hinders the escape of the contents of the stomach. Hence follows, as Glenard[7] points out, a further tendency to dilatation and sinking of the stomach.

Another functional disorder of the stomach is gastric irritation or catarrh, generally caused by irritating ingesta. In the first stage there is increased secretion of the gastric juice (especially of hydrochloric acid) as well as increased peristalsis, these being compensatory and promoting the early evacuation of some of the contents of the stomach. The over-activity, however, is soon followed by exhaustion and impaired motor activity, as a result of which any food remaining in the stomach tends to ferment, setting up much the same circles as have been mentioned under atonic dyspepsia. In fact, the two conditions are closely allied.

Acute and chronic gastritis are severer disorders than those so far dealt with and are provoked by acute irritation or by excessive quantity of food. The associated morbid circles are similar to those already described but are complicated by an inflammatory condition. Ewald[8] gives the following description: "In diesen Fällen kommt es zu einer Störung der Saftsecretion und der motorischen Function des Organs, als deren Folgen entzündliche Processe der Schleimhaut entstehen, die ihrerseits wieder auf die Secretion verzögernd oder hemmend einwirken, woraus sich dann ein Circulus vitiosus in optima forma entwickelt. Derselbe wird durch die Bildung abnormer Zersetzungs- und Gährungsproducte . . . unterstützt." Another form of circle is associated with gastric ulcer, a disease from which recovery is often incomplete, leaving behind it a liability to relapse, and a diminished power of resisting fresh attack. The resulting lesion increases with each relapse until the cumulative effect may be extensive. Doubtless the impaired general nutrition due to the ulcer has some effect in rendering the mucosa less able to resist the extension of the mischief.

Somewhat wider circles embrace the intestines, the liver, in fact, the portal area. If, for example, imperfectly digested food escapes through the pylorus a catarrh of the intestines is set up which in its turn is reflected on the stomach. Ewald[9] goes so far as to say that this vicious circle (*Zirkelschluss*) is formed in all diseases of the stomach. Equally intimate is the correlation between stomach and liver. Every gastric and intestinal derangement reacts on the liver, while conversely every liver derangement reacts on the stomach. Lauder Brunton[10] who noticed how the composition of the blood made to circulate through an excised liver affected the rate of flow, suggests the following explanation: "Indiscretion in eating or drinking disturbs the digestive processes in the stomach and intestines; the products of imperfect digestion or of decomposition in the intestine being absorbed into the veins pass to the liver; they may there induce an obstructed flow through the hepatic capillaries; the venous blood returning from the stomach and intestines will no longer be able to find an easy passage into the general circulation, and venous congestion of the stomach and intestines will be the result. Such venous engorgement as this will interfere with gastric and intestinal digestion, and this again will react on the liver. Here, then, is a vicious circle which it is necessary to break."

The second division of circles relates to the stomach in its, so to speak, foreign relations, in its relations to organs unconnected with digestion. Hippocrates[11] has a famous aphorism:—

ὥσπερ τοῖσι δένδρεσιν ἡ γῆ, οὕτω τοῖσι ζώοισιν ἡ γαστήρ

(What the soil is to the tree the stomach is to the animal), and it is on this relation of the stomach to the animal that many circles depend. If the animal is out of health the stomach suffers. If the stomach is out of health the animal suffers. This vicious circle embraces the problem of nutrition in all its ramifications. But some organs are more susceptible than others. The delicate tissues of the central nervous system would on *a priori* grounds be likely to suffer early from gastric disorder, and such is found to be the fact. Defective nutrition of the nerve centres secondary to mal-assimilation quickly reacts on the gastric functions, stomach and brain reciprocally embarrassing each other. Worse still, if in consequence of stasis and decomposition of food poisons are brewed and the blood which should nourish the nerve tissues is itself tainted. Can one wonder that under such conditions a tangle of interactions is set up which it is not easy to unravel?

In neurasthenia, whether of spontaneous or of traumatic certainly earned the right to be heard, and his conclusions deserve the careful study of all who investigate this subject.

[11] Περὶ χυμῶν, § 11.

In the present work we find an immense amount of material which should prove of great value, and though we cannot endorse all the writer's conclusions we may at least express our appreciation of the manner in which he has carried out his task. In a chapter devoted to the geographical distribution of cancer a *résumé* is given of the frequency of malignant disease in different parts of the world, but it is certain that for many countries no real data are available. As to the increase of cancer the author considers that it is attributable to a general increase of material prosperity and urbanisation, or, as he says elsewhere, "out of these conditions, which comprise a more domesticated mode of life, want of proper exercise, and excess of food, I believe the present increased cancer mortality has sprung." Later we are told: "Probably no single factor is more potent in determining the outbreak of cancer in the predisposed than excessive feeding."

"Jensen's tumour" is not admitted to be cancerous by Mr. Williams but he does not appear to be aware that many other strains of inoculable tumours have been discovered and that these tumours are "cancerous' both histologically and clinically. In this connexion we might perhaps point out that in a subject so complex and uncertain as the etiology of cancer there is room for several opinions and that to dogmatise in the present state of our knowledge is hardly justifiable. The reader of Mr. Williams's work cannot fail to be struck by the very wide extent of his reading and no one will deny that he has accumulated an immense mass of facts, and inasmuch as references are given for nearly all the statements made the book will prove very useful to all workers on the subject of cancer.

A System of Medicine by Many Writers. Edited by Sir T. CLIFFORD ALLBUTT, K.C.B., M.A., M.D. Cantab., D.Sc., F.R.C.P. Lond., F.R.S., Regius Professor of Physic in the University of Cambridge; and HUMPHRY DAVY ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond., Senior Physician, St. George's Hospital, Physician to the Victoria Hospital for Children. Vol. IV., Part I. London: Macmillan and Co., Limited. 1908. Pp. 764. Price 25s. net.

THE new edition of this "System of Medicine" will prove to be considerably larger than its predecessor; this is a matter of necessity, since much valuable work has been accomplished since the first edition was published. Any curtailment which would render necessary the omission of new knowledge, theoretical or practical, would naturally diminish its value and is therefore rightly to be deprecated. The editors have fully appreciated this principle and have acted accordingly. The fourth volume of the original System of Medicine has now been divided into two. The sections on Diseases of the Nose, Pharynx, and Larynx, which were originally condensed into 200 pages, have been removed and now, greatly expanded and accompanied by a section on Diseases of the Ear, will appear in a separate volume as Part II. of Vol. IV.

The present instalment, Part I. of Vol. IV., which contains the Diseases of the Liver, Pancreas, Ductless Glands, and Kidney, has undergone very considerable changes. Dr. A. Keith writes on the Anatomy of the Liver, and in a new article on Hepatoptosis supplements, so far as the liver is concerned, the more general article on Visceroptosis in Vol. III. He speaks favourably in regard to the operative treatment of hepatoptosis, quoting the 18 cases collected by Terrier, of which 15 were cured, one died, and in two the result was unknown.

Dr. William Hunter has supplied a new article on Delayed Chloroform Poisoning,' and after a criticism of the views hitherto held on the subject arrives at the conclusion that the condition is essentially a toxæmia of hepatic origin due to the poisonous action of chloroform on the liver cell, already depressed in its functional activity by pre-existing causes involving deficiency of carbohydrate food material and by excessive tissue proteolysis. The fat changes which are found are at once the expression of this deficiency and the measure of the degree of strain placed upon the cell in maintaining its energy. The various diseases connected with the blood-vessels of the liver, including multiple abscesses and suppurative pylephlebitis, are described by Dr. W. P. Herringham.

The article on Cirrhosis of the Liver has been rewritten by Dr. H. P. Hawkins. His remarks on the etiology of the condition are worthy of note. He concludes that alcohol is the predominant cause of the disease, but he also states that it is open to question whether its action on the liver is direct and immediate or whether some other factor is intermediate or conjoint. The view is widely held that alcohol should be regarded not as the immediate cause but rather as predisposing to, or assisting the action of, some other poisonous agent which is not yet actually determined; this agent may possibly be of a bacterial nature. Dr. Hawkins further shows that it is beyond question that a non-alcoholic portal cirrhosis is occasionally met with in adults, more commonly so in children, and evidence is forthcoming to support the hypothesis that this form of cirrhosis may have a toxic origin. Dr. H. Morley Fletcher contributes a new article on Biliary Cirrhosis. He describes two recognised forms: (1) hypertrophic biliary cirrhosis (*Hanot's disease*), and (2) obstructive biliary cirrhosis. An article on Tuberculosis of the Liver has been written by Dr. W. Hale White, and one on Syphilis of the Liver by Dr. Hawkins.

In place of the valuable contribution to the first edition of Dr. Fitz of Boston, U.S.A., new articles on Disease of the Pancreas have been written by Dr. W. C. Bosanquet and Dr. G. Newton Pitt. In describing chronic pancreatitis Dr. Bosanquet mentions that among the toxic causes of this condition the most important is probably the abuse of alcohol; he also alludes to the fact that in the majority of cases of cirrhosis of the liver the pancreas is simultaneously affected. The vast majority of cases of fibrosis of the pancreas are only discovered on the post-mortem table, and it is clear, therefore, that mild degrees of the affection can run their course without giving rise to any characteristic symptoms. Dr. Newton Pitt gives a good account of tumours, cysts, and calculi of the pancreas. For purposes of convenience the descriptions of infantilism (Dr. John Thomson), obesity and adiposis dolorosa (Sir Dyce Duckworth), and œdema (Professor W. D. Halliburton) are appended to the section on Diseases of the Ductless Glands.

Professor G. R. Murray has written a new account of Myxœdema. In discussing the treatment of the disease by preparations of the thyroid gland, he expresses the opinion that the liquor thyroidei yields the best results. The liquid should be freshly prepared once a fortnight and be prescribed undiluted; the patient should be instructed to measure out the required dose in a minim glass and to add a dessertspoonful of water. The other articles on Diseases of the Thyroid Gland have been almost rewritten by Dr. Hector Mackenzie.

Acromegaly now finds a place in this volume instead of in Volume III., as in the previous edition, and is described by Professor E. F. Trevelyan. In stating the various therapeutic measures which have been tried in connexion with this disease he suggests that when headache is intractable trephining deserves a trial; the operation has already been proved to be of service in a few cases.

Bacteriological research has brought to light a circle associated with cholelithiasis. In a large proportion of attacks micro-organisms that have reached the gall-bladder excite a catarrh of its mucous membrane, which results in a disintegration of the epithelial cells, amongst which cholesterin, bilirubin-calcium, and micro-organisms are deposited. In course of time these become aggregated into biliary calculi, which in their turn keep up the catarrhal condition to which they owed their origin. A circle may also be set up in those cases of appendicitis which are followed by recovery although there is no *restitutio ad integrum*. Recovery is at the cost of some permanent anatomical lesion and of lessened resistance to fresh attack. The first attack has bequeathed a liability to recrudescence on trivial provocation and each time the lesion increases. The acute attack and the lowered resistance act and react on each other, ending but too frequently in a fatal catastrophe.

Mention has already been made in Group II. of the circle associated with a failing heart and an impure blood-supply due to visceral congestion and stasis. If the stasis is so severe as to lead to ascites (including hydrothorax and hydropericardium) the abnormal pressure conditions will aggravate the heart failure and set up a condition of grave peril to life. The ascitic effusion, by pressing on the renal veins, may also impede the excretion of urine; the impeded excretion further increases the ascites.

GROUP IV.—*Circles associated with the rectum and anus.*

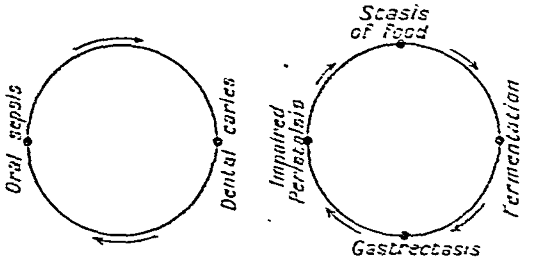
Various circles occur in conjunction with constipation[23] and defæcation. Dilatation of the rectum and constipation, for example, stand in reciprocal relations, each condition acting and reacting on the other. If fæcal masses remain long in the intestine or in the rectum, much of the contained liquid undergoes absorption, the fæces being converted into dry and scanty scybala. In course of time these scybala may cause obstruction and further increase the constipation, fæcal stasis being both cause and effect of fæcal stasis. Constipation is frequently complicated with hæmorrhoids, anal fissure, ovarian tenderness, or even trigeminal neuralgia,[24] all of which, owing to associated pain, cause inhibition of peristalsis and consequently aggravate the constipation. Strümpell[25] has drawn attention to the occasional connexion between neurasthenia and constipation. "The nervous affection ...... is often probably the primary disease, which is followed by constipation, while in other cases the habitual constipation leads secondarily to the nervous depression. The two conditions usually form a vicious circle, since each of them is able to keep up and to increase the other." Two circles may be met with in prolapsus recti. Prolapse causes tenesmus; result of the tenesmus—increased prolapse; prolapse also causes relaxation of the sphincter; result of the relaxation—increased prolapse.

An illustration of an infective circle occurs in persons whose rectum is infested with oxyurides. The consequent itching and scratching lead to the helminths or their ova being caught under the nails, conveyed to the mouth, and swallowed by the host. From the stomach the ova reach the intestines and rapidly attain maturity. Thus the irritation secures by auto-infection successive generations of the parasite. The present vogue of quack aperients and the impatience of over-zealous disciples of Æsculapius are responsible for the artificial circle often set up by the injudicious use of cathartics. The irritation of the mucous membranes brought about by indiscriminate drugging depraves the secretions and produces a condition which is urged in proof of the need of further evacuations. "And thus the practice proceeds in a vicious circle of habit from which the patient is rarely extricated without more or less injury to his future health."[26] The constipation is relieved but only to be followed by more obstinate constipation requiring stronger aperients.

Enough has been said to indicate the frequency of vicious circles in disorders of the digestive system. The list, however, is far from exhausted, for the various functions of the body are so linked together that disturbance of the equilibrium existing between them radiates far and wide, cause and effect acting and reacting continuously on each other. It was well said by Paget[27] that "the health of each part is a necessary corollary of the health of all the rest." Equally true is it that disease of one part involves disease of all the rest.

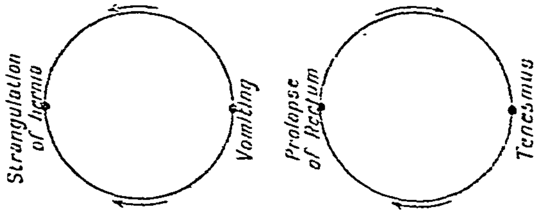
Conclusion.—The ἰατρὸς πολύτροπος may sometimes anticipate and prevent the establishment of a vicious circle if he is familiar with the course of pathological processes and intervenes at the right moment. *Melius est prevenire quam preveniri.* When a circle is present, a recognition of the reciprocally acting forces will solve many an enigma in obscure disease and pave the way for rational treatment. The graphic method of analysing a circle into its two, three, or more component factors, as shown in the accompanying diagrams, will be found of considerable assistance (cf. Figs. 1 and 2).

FIG. 1.



Oral Circle Gastric Circle

FIG. 2.



Intestinal Circle Rectal Circle

In the matter of treatment the removal of the exciting cause will at times insure recovery. Or the weakest link in the chain of actions and reactions may be snapped and the circle broken. In yet other cases each of the factors acting reciprocally on each other must be attacked. Never should it be forgotten that the presence of a vicious circle is a *signum mali ominis*, tending to aggravate and perpetuate disease. The wise physician will adopt as his motto the words of Ovid—

> "Principiis obsta; sero medicina paratur,
> Cum mala per longas convaluere moras."

Reading.

MULTIPLE VESICAL CALCULI.*

BY WILLIAM J. MALONEY, M.D. EDIN.,
RESIDENT MEDICAL OFFICER, KASR-EL-AINY HOSPITAL, CAIRO.

CALCAREOUS matter in urine was formerly termed sand, gravel, or stone according as it occurred in crystalline deposits, small, or large concretions. Natural characters by which to differentiate these forms were unknown, so arbitrary standards, based on a common property, weight, were used. Thus, Sir Henry Thompson[1] taught that a vesical concretion should not be deemed a stone unless it weighed at least 20 grains; this was rather an exacting standard, especially for concretions of low specific gravity, and it disdained as gravel what were indubitably stones. But the researches of Rainey, Ord,[2] and Carter[3] have shown that all stones contain colloid material as a characteristic and essential constituent which naturally distinguishes them from any other form of calcareous deposit. A concretion free from colloids is not a calculus; conglomerations of

---

[23] Some of these circles associated with constipation might equally well have been placed in Group III., but for convenience sake are grouped together here.

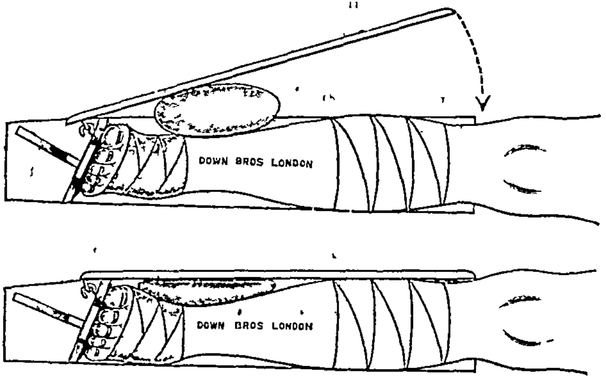
New Inventions.

A NEW SPLINT FOR THE TREATMENT OF POTT'S FRACTURE.

I HAVE designed, and Messrs. Down Brothers have made, a new splint for the treatment of Pott's fracture. The apparatus consists of a short back splint with the foot-piece set at an angle to the back piece of about 30 degrees, so that the foot is brought into a position of inversion. There is also a single side splint of the same length as the back splint. The side splint is provided with two rings at its lower end, which fasten on to two hooks below the foot-piece at its inner end. When the leg has been fixed on the back splint a large pad is applied to the inner side of the ankle. The side splint is then brought up to the back splint and fixed with a bandage carried round both back and side splints. The side splint thus acts as a lever of the second order, the fulcrum being the hinge which fastens it to the foot-piece of the back splint. The lever makes pressure through the pad on the inner side of the ankle, above the inner malleolus, and forces the leg outwards, thus reducing the outward displacement of the foot, and the broadening of the limb above the ankle-joint due to separation of the malleoli. The splints do not reach up the leg as far as the knee, so that the limb can be put up with the knee in the flexed position.



GEORGE WILKINSON, M.B., B.C. Cantab., F.R.C.S. Eng.,
Honorary Surgeon to the Sheffield Royal Hospital.

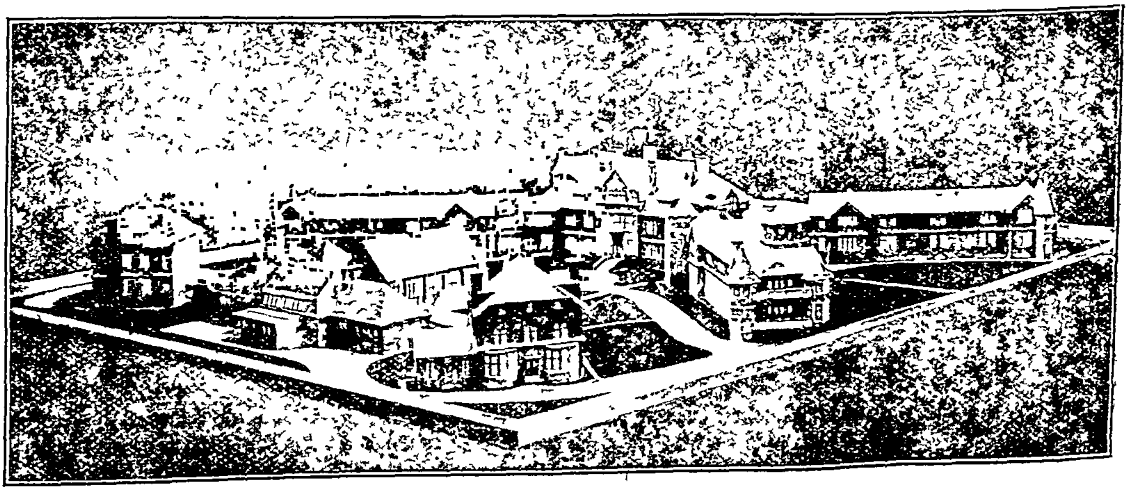
ELECTRIC ILLUMINATION FOR DIAGNOSIS.

Messrs. F. Davidson and Co. of 29, Great Portland-street, W., have shown us a very efficient and complete outfit for electric illumination of the eye, ear, nose, &c., and also for transillumination. The source of energy consists of what appears to be a very good form of dry cell. Two of these are fitted in each case but one is usually sufficient and the second, by a very simple device, can be thrown into circuit when the first shows signs of exhaustion. The small lamps give a very brilliant white light (but the intensity can be reduced if desired) which gives a very good transillumination of the antrum, &c. The set comprises the firm's new patent electric ophthalmoscope. There is also a full set of aural and nasal specula, a twin lamp for transillumination, and a cautery handle with some cautery burners, as well as extra lamps. If care be taken not to turn on the current longer than is actually required from 12 to 18 burnings can be done with the cautery before the cell is exhausted, and even after this the cell can be used for a considerable time for light. The cells cost 3*s*. each. The whole is contained in a very compact wooden case which is light and easily portable. It should prove of great use and convenience to specialists and others.

THE FRIMLEY SANATORIUM.

FROM all the civilised countries of the world there were sent to the International Congress on Tuberculosis at Washington exhibits in the form of drawings or models or both to show what was being done in the way of sanatoriums, and among these the sanatorium of the Brompton Consumption Hospital at Frimley received the great distinction of sharing the first prize with the Whitehaven Sanatorium, Pennsylvania. We may add that the Brompton Hospital received the first prize for institutions for the treatment of advanced cases.

We have already described this sanatorium at some length in THE LANCET,[1] giving also a ground plan and a picture of one elevation; we now show a reproduction of a photograph of the model which was exhibited. The model was made, to a scale of eight feet to the inch, coloured after nature, with real gravel paths, the grass being of green cloth. Our readers can see well from the illustration the plan of the building. The eight groups of buildings consist of the following: (1) gate lodge; (2) laundry; (3) engine and boiler house, with engineer's residence; (4) pathological block with mortuary, all placed near the road for convenience of delivery of coal, &c., and for keeping any hearse out of the grounds; (5) the patients' wards and the administration; (6) assembly hall, dining-rooms, kitchen, and stores; (7) medical officers' residence; and (8) nurses' home



Reproduction of a photograph of a model of the Frimley Sanatorium.

The problem which the architect, Mr. Edwin T. Hall, vice-president of the Royal Institute of British Architects, set himself to solve was to design the patients' building, so that there should be a minimum of distance from the administrative centre to the farthest ward; there should be only two storeys (ground and first floors) of wards, and the building should be divisible into units to admit of elasticity of classification and segregation. This eventuated very well in the design adopted

[1] THE LANCET, August 5th, 1905, p. 398.

with the future water-supply needs of B and C so long as it can procure for itself an adequate supply of pure water. We do not think that there is much difference of opinion amongst those who have studied the water problem as to the pressing necessity before the water-supplies of the country are all appropriated of acting upon the recommendation of the members of the Royal Commission on Sewage Disposal, who in their third report proposed the formation of rivers boards which should have control over all the matters referred to and whose work should be focussed in some central authority. It is doubtful whether a measure comprising these recommendations would have to be regarded as a contentious one and, this being so, it is not easy to understand why the recommendations of the Commission have not as yet been acted upon.

"The Human Woman."

THERE can hardly be two opinions as to the importance of the question which is so prominently before the public at the present day. The questions of the civic and political status of women cannot be shelved nor do really thoughtful people desire to shelve them, however much they may resent some of the methods which have been adopted by a certain section of women. There is at the present moment a solid body of responsible opinion desirous of attaining the ends advocated, though certainly retarded, by these women, and conscientious citizens cannot afford to ignore this fact. Times have changed. The wilderness in which such prophets as JOHN STUART MILL and JOHN STUART BLACKIE raised their voices in the last century has become peopled by an advancing army no longer to be brushed aside as a group of idealists or despised as a "shrieking sisterhood." With the views of philosophy, however, though they have undoubtedly become of late more favourable to women's claims, we are not here concerned; we are considering only the arguments put forward by an army of women who are prepared to make intellectual rather than physical assaults upon the doors of political institutes hitherto sacred to their husbands and brothers. A very spirited assault of the former order has been delivered by Lady GROVE[1] in a book which we are constrained to think will become a powerful weapon in the armoury of her cause. "The Human Woman" is a book which merits the careful consideration of her opponents, for if they can silence her arguments effectually they will strengthen in a material manner the case for restraining women from sharing equal political rights with men. The evidence, for instance, adduced from the State of Wyoming where women's suffrage has been in force for a quarter of a century deserves careful consideration, and Lady GROVE's essay on "War and Woman's Suffrage" contains a shrewd refutation of the doctrine that only those who are prepared to defend the country with their bodies should have a voice in controlling its destinies. Indeed, the logical application of this doctrine would notably reduce the present suffrage. But although we are not concerned to discuss this question in its political bearings there are certain aspects of it which fall within the legitimate province of a medical journal and which are of vital moment to the topic.

We do not propose to deal directly with Lady GROVE's principal theme, the case for women's suffrage, but with what appears to us the inevitable sequel to its attainment,—the claim of women to enter Parliament, for they would hardly rest content to elect candidates not of their own choosing. To meet this problem she has written a chapter headed "Women in Assemblies," in which she seeks to show that the success of women on Local Government bodies justifies their promotion into Parliament itself should the country really desire it. Now here is the crux of the whole matter. In the first instance we may ask, "Do the women of the country really desire the suffrage, to say nothing of executive responsibility in Parliament?" a question of which Lady GROVE acknowledges the force; and secondly, are women as a whole as fitted mentally and physically for the business of legislation as are men? The question is so weighty that it must be decided upon general principles and not upon the performances of exceptional women. It is true that women have served, and are serving, with distinguished success on Local Government bodies, as many prominent men of affairs have testified in the book under discussion, but we submit that these are picked and pioneer women and hardly representative of the "average woman," and that they are, moreover, shining in a sphere where men have failed signally to realise their responsibilities. More honour to them, certainly, and more discredit to men grown careless, but nevertheless the case by no means necessarily applies in the affairs of Parliament to which its active members are accustomed to devote their talents strenuously and wholeheartedly. Are women fitted to supplement or to supplant men in the direct counsels of the nation, having regard to their mental equipment and physical disadvantages? We may say at once that we are convinced that a greater fundamental psychical sex difference exists between the average man and the average woman than Lady GROVE will admit, and we are further convinced that the preponderance of executive ability—the broad grasp of detail, the capacity of selecting the essential fact, and of seizing the decisive moment—resides in the masculine rather than the feminine mind. The talented author doubtless will disagree with us with vivacious eloquence and we have no other proof to support the faith that is in us than an appeal to experience, and we fear we shall hardly propitiate her or excuse our presumptuous attitude by confessing freely that the opposite sex possesses other and perhaps more glorious attributes of no less moment for the welfare of the race. We mean by experience rather a general experience of men and women than an examination of history; it would be hardly fair to point to the rarity of distinguished women, as compared to distinguished men, in every branch of human activity except those of the domestic life, in the past, for this may have been due to the handicap of their education—or lack of it—and of the convention of their upbringing. At the same time this has not prevented the sporadic appearance of genius amongst women—the recently deceased Dowager Empress of China affords a notable instance—but such genius has been infinitely stones were removed one by one by my finger and a scoop, while an assistant made pressure through the rectum and abdomen so as to keep the mass applied to the wound in the neck of the bladder and to afford some resistance to the delving action of the scoop; after 30 minutes 121 separate stones were thus removed, together with much friable débris like powdered chalk and the great globular mass in the bladder had disappeared; one large oval stone of about the size of a duck's egg still remained, situated about the fundus of the bladder which was so contracted around it as partially to embed it. As it was too big to extract unbroken I partially crushed it with forceps and carefully extracted the fragments. The bladder was drained through the perineal wound and washed out night and morning with boric acid solution. Ten days after operation the urine, which still contained pus in small amount, was passing in about equal quantities by the wound and by the normal route; in three weeks the perineal wound was quite healed, the urine was acid, and only a few pus cells and red blood corpuscles could be detected microscopically.

---

[1] The Human Woman. By Lady Grove. London: Smith, Elder, and Co. 1908.

Six days after the operation the patient developed a virulent ulcerative stomatitis which rapidly spread till it involved almost the entire alveolar margin and exposed patches of bare bone on both maxillæ; this infection, without any rise of temperature, continued unabated for nine days and then began steadily to die down. His general condition improved considerably as his mouth healed but he contracted acute dysentery and died within 36 hours, on the twenty-sixth day after the operation.

The following is a *précis* of the post-mortem report furnished by Dr. A. R. Ferguson, professor of pathology, School of Medicine, Cairo. "Peritoneum normal. Bladder slightly enlarged, rather thin-walled; on inner surface superficial areas of yellowish discolouration (? necrotic) and a few small ulcers but otherwise mucous membrane healthy; pus exuded from orifice of left ureter. Kidneys, normal size, both very soft, capsules non-adherent; diffuse purulent infiltration of substance without definite abscess formation: ureters normal. Intestines, colon distended with large quantity of altered blood: extensive superficial ulceration suggestive of acute dysentery. Spleen, weight 150 grammes, soft atrophied pulp; does not suggest septicæmia. Liver, slight fatty infiltration; no gross lesion. Heart, soft, flabby, fatty muscular walls, no valvular lesion. Lung emphysematous; congested and œdematous at bases. Bilharzial worms were present in the portal blood. The relatively healthy condition of the bladder post mortem may have been due partly to the toleration alleged to be characteristic of the oriental bladder and partly to the rounded shape and immobility of the mass of stones. There was no appearance of calcareous matter in either kidney or ureter."

Mr. W. M. Colles, B.Sc., assistant professor of chemistry, kindly analysed a few of the small stones. They consisted of: Ammonium magnesium phosphate, calcium carbonate, ammonium urate, and calcium oxalate (traces). The large stone was of similar composition but contained relatively more urate.

As bilharzial ova were present in the urine I looked for them in four stones but found none.

The case was admitted to the wards of Mr. F. C. Madden, who kindly allowed me to operate and to conduct the after-treatment.

Cairo.

THE DIAGNOSIS AND TREATMENT OF PANCREATITIS.[1]

By D. CHALMERS WATSON, M.D. EDIN., F.R.C.P. EDIN.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

I HAVE often thought that one of the most interesting studies in medicine is the history of the stages in the evolution of our present knowledge of a particular disease or group of diseases. This is well exemplified in the case of pancreatitis. In the year 1672 Tulpius described pancreatic abscess of pyæmic origin; in 1799 Matthew Baillie describes what he calls a hard pancreas with the lobules distinct, which is what we now should call a case of chronic interstitial pancreatitis, and the same author figures a case of pancreatic calculi, carefully dissected, showing the relation of the bile and pancreatic ducts. Percival, in 1804, described a case of acute suppurative pancreatitis following an attack of acute gout, and Balser in 1879 first described acute pancreatitis with fat necrosis. No general attention was attracted to the subject, however, until Fitz ten years later published his important papers. The surgical study of the inflammatory diseases of the pancreas in recent years may be said to be the result of an inquiry into the causation of some of the complications of gall-stone disease, and, as W. S. Mayo has pointed out, our present knowledge of these affections is largely due to Mayo Robson who first noticed the disease in connexion with his operative work upon the biliary tract. This knowledge can hardly yet be spoken of as common knowledge, since many recent works on medicine give little or no attention to the subject; and in this connexion it is of interest to note that in the Transactions of our own Society there is no paper on this important subject.

The comparative frequency of the disease and the brilliant results which follow operative interference may be gathered from the writings of Mayo Robson, who, as far back as 1904, pointed to a record of 102 operations undertaken in patients where chronic pancreatitis constituted the chief disease, or where it formed the chief complication of the disease, with 96 per cent. of recoveries, giving a mortality of 3·9 per cent. An admirable survey of recent literature on the diagnosis and surgical treatment of subacute and chronic pancreatitis is given in Robson's and Cammidge's recent work on the surgery and pathology of the gland.

My interest in this subject was aroused in the course of the autumn of last year through the admission to Sir Thomas Fraser's wards, then under my care, of a case of chronic pancreatitis, in which this diagnosis had previously been established by operation. Through the kindness of Sir Thomas Fraser I was later able to show you this patient, who, I regret to say, succumbed some months later. My investigations of this case led me to make a lengthy investigation into the reliability of the so-called pancreatic reaction in the urine, a test devised by Cammidge and relied on by Robson as of great value in the diagnosis of pancreatic deal with it by operative procedures. The only operation which has been employed to any extent for spinal caries has been laminectomy and that has only been performed for consecutive paralysis, and there is no doubt that the general surgical opinion in this country is opposed to this operation for paraplegia following caries of the spine. The pressure on the spinal cord which leads to the paralysis, whether it acts directly or by the setting up of a transverse myelitis, is but little likely to be relieved by removing the laminæ of one or more vertebræ. The exudation mass giving rise to the pressure, for it must be very rare in spinal caries for the bone itself to exert any pressure on the cord, is situated at the anterior part of the spinal canal immediately behind the vertebral bodies and to a small extent on each side. It might therefore be reasonably expected that the mere removal of some laminæ would have no, or little, effect on the pressure exerted on the anterior aspect of the spinal cord. The results obtained by laminectomy support this theoretical conclusion. It is true that occasionally the paraplegia diminishes after the operation, but the proportion of cases in which this occurs is no greater than in those where the paraplegia is treated by prolonged rest in bed. It has therefore come to pass that most surgeons limit themselves to opening abscesses in cases of spinal caries but do not undertake any further operative procedures.

---

[1] A paper read before the Edinburgh Medico-Chirurgical Society on Nov. 4th, 1908.

Dr. KIRK has confined the operations which he has performed to caries of the dorsal and lumbar regions, for in these the tuberculous disease is as a rule limited to the body of the vertebra, while in the cervical region it extends into the pedicles and the laminæ, and in the sacrum the whole bone is usually involved sooner or later. This limitation of the disease to the body in the dorsal and lumbar regions renders the lesion more amenable to treatment and more accessible to surgical interference. When a student and as a resident Dr. KIRK tells us that he saw several laminectomies done for paraplegia from caries and later he performed the operation once, but in all these cases the results were unsatisfactory. In 1896 he was asked to operate on a child who had suffered for long from complete paraplegia due to caries of the dorsal spine. He performed a costotransversectomy or MÉNARD'S operation with very good results. He was so satisfied with the effect of the operation in this case that he employed it in several other similar cases and in all the paraplegia disappeared. He was so much impressed by the success which he had attained that he employed MÉNARD'S operation in cases of spinal caries where no paraplegia was present but with palpable lumbar, iliac, or psoas abscesses; he evacuated the pus and removed the carious or necrotic bone. The results in these cases also were favourable. Dr. KIRK then determined to employ the same operation in early cases of spinal caries, for he was dissatisfied with the results of the usual treatment of such cases by prolonged rest in bed, fresh air, and good food, and the subsequent use of spinal supports. In early cases the disease is limited to the body of one vertebra, and if this vertebral body be removed the adjacent bodies fall together, and Dr. KIRK finds that the deformity which follows is very slight. The results of those early operations were very satisfactory and now Dr. KIRK considers that it is the best method of treatment of early caries of the spine in the dorsal and lumbar regions. The statistics which he gives are not complete, for he has been unable to trace many of the cases; but the results so far as known are as follows. In all he has operated on 61 cases of dorsal and lumbar spinal caries. There were five deaths immediately due to the operation. Three of these deaths occurred in adults who had suffered from the disease for many years. In one of these fatal cases in adults the operation was abandoned early as the anæsthetic was badly taken and the patient died a few hours later. In all the other fatal cases the patients had large abscesses. In all of the cases in which paraplegia was present the patient recovered from it after the operation. In ten cases with large abscesses the suppuration continued and eventually the patients died. The majority of the cases left the hospital in good general health, with sinuses discharging a small amount of pus, and in many of these when seen later the sinuses had healed. In 14 cases the wounds were completely healed before the patients left the hospital. The statistics, incomplete though they are, support, in Dr. KIRK'S opinion, his plea for early operation before any abscess has developed or pressure paraplegia has occurred. It is certainly worthy of note that not a single case died after the operation when performed at an early stage. The rate of mortality rises with the extent of the disease, the amount of abscess formation, and the presence of pressure effects on the cord.

The operation is as follows. A vertical incision is made immediately to the outer side of the tips of the transverse processes. If an abscess or a sinus or any indication of pressure on a nerve exists on one side the incision is made on that side, but if no indication exists the operation is performed on the right side. The centre of the incision should be opposite the vertebra affected, and it must be borne in mind that the most prominent spinous process belongs to the vertebra immediately above the carious body. The transverse processes of three vertebræ should be exposed, and in the dorsal region an inch of the ribs external to the tubercle should be cleared and the pleura should be carefully separated, for it is easily perforated. The ribs are then cut through with forceps and the transverse processes are also divided and these portions of bone are removed. The soft tissues are raised from the pedicles and sides of the bodies by a periosteal elevator and the carious bone is readily found. The hæmorrhage may be troublesome and this is best avoided by using the scalpel as little as possible. Three transverse processes require to be removed to give free access to the affected body. The carious bone is removed and then by means of a chisel or gouge the anterior and lateral walls of the cavity must be taken away so as to allow the level surfaces above and below to fall together and to obliterate it. The cavity is cleared out, dried, and packed with sterilised gauze soaked in a solution of picric acid. The superficial part of the wound may need to be reopened later. As soon as possible after the operation the patient is allowed to sit up, so as to bring together the bony surfaces; a spinal support is never employed. We have described the operation somewhat fully so as to enable surgeons to judge of the method employed. It is difficult without more ample statistics to form an exact opinion of the value of this method of treatment.

malignant disease of the gland, a fact of great practical importance. In appraising the value of this diagnostic measure we must, of course, keep in view the fact that a certain proportion of cases of malignant disease is complicated by general catarrhal or interstitial changes throughout the gland.

My third group leads me to refer to the etiology of so-called catarrhal jaundice. Mayo Robson, Sidney Phillips, and other writers have previously suggested that certain cases which are at present regarded as "catarrhal jaundice" may really be "acute pancreatitis," the blocking of the bile-ducts being the result of pressure from an enlarged and swollen head of the pancreas. In the course of the past year I have had the opportunity of, I think, establishing the correctness of this view. I have examined the urine of five cases of so-called catarrhal jaundice, four of which were personally observed. In three of the five there was a marked pancreatic reaction in the urine and in these cases a striking clinical feature was tenderness on deep palpation over the region of the head of the pancreas; in the remaining two the reaction was negative and free palpation of the abdomen in the region of the pancreas failed to elicit any pain. On the strength of these facts I venture to suggest that those cases of catarrhal jaundice which are associated with a well-defined area of tenderness in the region of the head of the pancreas are in reality cases of pancreatitis. The next case is typical of a group in which the pancreatitis is secondary to ulcer of the stomach or duodenum.

CASE 3.—A woman, aged 28 years, consulted me on account of pain in the abdomen and back and vomiting, the symptoms being of eight weeks' duration. Some years previously she had suffered from gastric ulcer. The pain radiated to the left side, its onset had no immediate relationship to the taking of food, and it persisted for some hours. On examination I found marked tenderness on deep pressure one inch above the umbilicus and to the right, the area of pain extending for about two inches, with dulness on percussion over the affected area. The motions were unformed, pale, and fetid; no microscopic examination was made. There was no febrile disturbance. Under treatment the condition gradually improved, all symptoms disappearing in four weeks, and for the past eight months the patient has enjoyed very good health. In this group I have seen two cases complicated by glycosuria, and one, a male patient under the care of Professor W. S. Greenfield, who developed glycosuria and also melæna when under observation in hospital.

Lastly, I will refer very shortly to the occurrence of pancreatic disease in some general constitutional conditions in which its existence has not, so far as I am aware, been previously recognised. I have notes of 20 cases of gout and rheumatoid arthritis and four cases of chronic alcoholism seen in private or in hospital practice in which the existence of pancreatic disease was determined by the presence of a marked pancreatic reaction in the urine with tenderness on deep pressure over the head of the gland. Since cases of gout, rheumatoid arthritis, and the like are in the majority of instances associated with a catarrhal state of the intestinal tract, as shown by the fetid state of the stools, &c., the existence of pancreatic disease in these conditions is not surprising, and its recognition is of practical importance from the point of view of treatment. I have on several occasions been consulted by patients who had previously been dieted for their gouty state along the familiar lines of a marked reduction in animal food, with relative and actual excess of farinaceous foods, in whom examination of the urine revealed a marked disturbance of the pancreatic function. In these cases recovery from symptoms followed the adoption of a diet—more protein, less carbohydrate—the advisability of which had been suggested by the results of urinary analysis. In this connexion it is of interest to refer to the observations of Dr. Katharine J. S. [illegible] of Craigleith Poorhouse, who, at my suggestion, made a histological examination of the viscera in some fatal cases of rheumatoid arthritis dying in the parochial hospital. In all the four cases examined striking pathological changes were present in the pancreas. I may add that more recently I have examined the urine of a case of rheumatoid arthritis in the same institution in which shortly before death the urine contained over 3 per cent. of sugar, and since this paper was written I have seen in Dr. A. Bruce's ward in the Royal Infirmary another patient with rheumatoid arthritis in which the urine contained 27 grains of sugar to the ounce.

Differential diagnosis.—It is not my intention to refer at length to the many points which are of value in the differential diagnosis of cholelithiasis and malignant disease of the liver or bile-ducts on the one hand and inflammatory or malignant disease of the pancreas on the other. My object is rather to record the results of my investigations into the reliability of recently devised tests for the determination of the existence of pancreatic disease and to refer to their practical importance both in diagnosis and differential diagnosis. The points to which I would draw attention may be shortly summarised as follows.

I. In cases of jaundice of doubtful origin assistance in the diagnosis is afforded by urinary analysis. (*a*) A negative pancreatic reaction points against the existence of pancreatitis. (*b*) In cases of cholelithiasis a positive reaction indicates pancreatitis and is very strong evidence that the stone is impacted at or near the duodenal end of the common bile-duct. (*c*) In cases where cholelithiasis can be excluded and the clinical features point to the existence of organic disease of the pancreas a negative pancreatic reaction points to malignancy.

II. Glycosuria, according to Mayo Robson, is of some value in the differential diagnosis of pancreatitis from malignant disease, this symptom being more common in inflammatory conditions of the gland. I have notes of four cases of malignant disease of the pancreas with distinct glycosuria, but it should be noted that these cases were all examined shortly before death.

III. The site and distribution of the pain have diagnostic significance. The pain of pancreatic disease is referred to the epigastrium and radiates to the left side; in disease of the gall-bladder and the bile-ducts the pain is referred to the right hypochondrium and radiates to the right.

IV. In acute cases with pain and pyrexia points strongly to an inflammatory affection.

V. Emaciation, anæmia, and asthenia may be present in pancreatitis to an extent equal to that present in advanced malignant disease.

With regard to pancreatitis unassociated with jaundice I would like to emphasise the following points.

I. In not a few cases of indigestion associated with flatulence, abdominal discomfort or pain having no distinct relation to food, constipation, and in some cases pale fetid stools, the primary derangement is to be found in the pancreas. In such cases a prominent clinical feature is the occurrence of pain on deep pressure over the region of the head of the pancreas.

II. In some cases of neurasthenia a marked pancreatic reaction is present in the urine. We have at present no data enabling us to determine whether this pancreatic disturbance is a result or a cause of the neurasthenic state.

Treatment.—In the early stages of the disease the inflammation subsides under simple remedial measures. The diet should be a light one and in cases where gastric symptoms are present an exclusive milk diet may be advisable for some days. Small doses of calomel frequently repeated, followed by a morning saline for two or three days, act beneficially in promoting a healthier state of the liver and small and large intestines. Where constipation is present, as it often is, one or more enemata may be called for. The pain may be relieved by ice-bags, hot fomentations, or, if necessary, subcutaneous injections of morphine. The excretory functions of the skin should be stimulated by an occasional Turkish bath, provided always that due care is taken in recommending such a measure and explicit instruction is given with regard to the necessary details. In the later stages the same rules apply. The diet should be carefully attended to, three meals a day at long intervals, sugar and starches being restricted, protein foods forming the staple of the dietary. With regard to drugs, in addition to calomel much value attaches, in my opinion, to lacto bacilline in the form recommended by Metchnikoff. An improvement in the state of the intestinal excretion may be rapidly attained and is shown in the character of the stools, which become formed and free of offensive odour. A course of intestinal irrigation has value in the same direction. In these cases it is of even greater importance to promote the functions of the skin and kidneys by appropriate baths and occasional diuretics. I have seen no decided benefit from the use of pancreatic extracts.

accommodation for 4530 million gallons which had been provided since the Board came into existence. That the £250,000 which this undertaking is to cost will be thoroughly well spent is certain, and this is made more certain by Dr. A. C. Houston's striking experiments upon the effect of storage of water upon typhoid bacilli, which we have reported in a previous article.[1] Where the money is to come from is another matter. The financial state of affairs disclosed at the meeting of the Board on July 17th last was eminently unsatisfactory, and still more unsatisfactory is the feeling which has been raised in the City by the new water assessment on the rateable value of business premises introduced by the Board. The late Lord Mayor, before retiring from office, presided at a meeting of protest against these charges which was held at the Mansion House, and we understand that in certain cases indignation has passed beyond the adoption of resolutions to the sinking of private wells, though this would not seem to be a means of escaping the rate. A body which exists for the public service is surely taking a wrong view of its functions when it adopts a policy which leads to this kind of retaliation.

THE CONTINENTAL HOTEL.

THE "hotel industry" has just had its International Congress in Rome, at which nearly every European country was represented. The motions submitted, discussed, and either carried or deferred to the Greek Kalends were numerous enough to convey an impression of the grave interests involved in the said "industry," but little was proposed, still less effected, in the way of innovation or reform so as to reassure the English-speaking contingent of the "great army of travel" that long-standing abuses would be done away with and long-desired conditions of health and comfort introduced in their stead. Much was said and something done as to the responsibilities of landlords in the matter of their clients' property when that has more or less mysteriously disappeared, if not left "in deposit" at the bureau; much debate, moreover, turned on the question of tips, *pourboires* or *mancie*—a question becoming yearly more clamant for solution; prominence was also given to the consideration of how to prevent the evils of competition, such as the spread of false news as to the health conditions of this or that rival resort, and kindred devices for detaining the client in one locality and preventing him from "patronising" another. These and questions of a kind more directly interesting to the landlord than to the public were duly formulated and considered; but nothing was said or even hinted at as to the essentials of sanitation in the hotel buildings themselves, as to the security of the *clientèle* in the matter of food and drink, as to the protection of the newly arrived guest from the "hotel rat," or *chevalier d'industrie*, so familiar to the travelling world on either Riviera. In fact, the "congressisti" in Rome committed the mistake that vitiates all the procedure of the cognate committee for "promoting the influx of foreigners into Italy," that of insisting on the secondary, and ignoring the primary, *momenta* in their brief. The committee referred to becomes eloquently expansive on the attractions, natural, historical, and artistic, of the Italian cities and the necessity of impressing these on an imperfectly appreciative world; but in ignorance of the fact that the said attractions are better understood and esteemed abroad than in Italy itself, it omits to satisfy the foreign guest (often an invalid) as to the health conditions of the locality which he affects as a place of sojourn, as to the quality of the food meted out to him, or the purity of the water-supply, or the genuineness of the wines offered for his consumption. Cases of poisoning from tinned meats or tinned fish have been frequent enough of late years to deter many an intending visitant from the scene of such a casualty; intestinal troubles of various kinds caused by adulterated wine or by "table-waters" that have long survived their *première jeunesse* have further reinforced the disposition to "fight shy" of the otherwise attractive sun-trap impressed with such or similar associations. The landlord interest is so intimately dependent on the reputation as to hygiene and diet enjoyed by the hotel that the wonder is that in such congresses as that just held in Rome, or on committees like those for the attraction of the foreigner, the medical consultant it not invited to bear a part in their deliberations. The advances made in hotel enterprise and organisation, in hotel management and comfort, are doubtless conspicuous and praiseworthy. We have but to recall the description of the mediæval inn in the "Colloquia" of Erasmus, or, better still, in Scott's "Anne of Geierstein," to realise the interval that divides the hostel available for the post-Renaissance travellers with the hotel he may alight at in any provincial town on the continent. But the superiority of the latter is still far short of what it might be, and the ideal hotel will continue to be a desideratum until the first conditions of health and comfort are provided in the direction above indicated—in the essentials of sanitation, local and domestic; of pure air and pure water; of adequate ventilation and genial "exposure"; of sound food, animal and vegetable; and of a choice of beverages, stimulating or non-stimulating, with which the "analytical chemist" of Dickens has as little as possible to do.

SUNLIGHT IN THE TREATMENT OF HIP DISEASE.

IN the *Canadian Journal of Medicine and Surgery* for November Dr. B. E. M'Kenzie has called attention to the value of sunlight in the treatment of hip disease. He began to treat cases of the disease in 1888 and in the first decade the mortality was about 10 per cent. In the next decade his results were much better. Careful scrutiny of the methods used showed that the improvement was chiefly due to the greater use of direct sunlight. The patient is kept upon a cot called a "Bradford frame." This consists of a rectangular frame about a foot longer than the patient and varying in width from 11 to 14 or 15 inches, according to the size of the patient, and covered with a sheet of canvas on which the patient lies. At each end is a bracket for attaching straps for extension and counter-extension. The patient is kept recumbent on this frame for months, not being allowed to rise even to the sitting posture. If much covering is necessary it may be wrapped around the patient and the frame and secured by safety-pins. A cage is thrown over the feet to prevent the bed clothing from resting upon them and producing a state of equinus or undue rotation of the limb and subsequent deformity. A pad is placed under the knee to maintain a few degrees of flexion. Extension is maintained by an anklet or gaiter with a buckle on each side from which a strap passes to the bracket at the lower end of the frame. Counter-extension is maintained by a pad in the perineum on the sound side round which passes a bandage to the bracket at the upper end of the frame. Dr. M'Kenzie finds this method of extension comfortable and more convenient than the use of a cord and weight. The cot can be carried from one place to another without disturbing the patient. Every day, whether in winter or summer, he is carried out of doors so as to be as fully exposed to the sun's rays as the grass. When the weather is suitable the affected part is exposed without any covering. This can be done during the greater part of the year without discomfort, and even in winter the patients are left out in the sunshine from morning till night on suitable days wrapped sufficiently prevented the cæcum from sinking into the pelvis; and (5) the value of appendicostomy in the treatment of constipation had now been demonstrated by experience.

---

[1] THE LANCET, July 25th, 1908, p. 255.

Mr. L. A. BIDWELL said that he was not convinced that a kinked or perforated appendix was worth preserving in the anterior wall of the abdomen. The cases of intractable constipation which he had seen treated by Mr. Keetley's method had done well.

Mr. J. P. L. MUMMERY pointed out that there were many cases of constipation in which appendicostomy was the ideal operation but there were many cases in which it was useless, therefore the cause of the constipation must be sought for.

Mr. S. G. KIRKBY-GOMES referred to the value of appendicostomy in the treatment of chronic constipation.

Mr. W. G. SPENCER described the appendix from a developmental point of view as nothing more than a shrunken tip of the cæcum and could not see how such a remnant could perform any important function.

Dr. A. F. HERTZ contended that it was easier to wash out the colon from the rectum than by means of an appendicostomy.

Mr. R. P. ROWLANDS urged that in the treatment of appendicitis it was better to remove the appendix than to leave it in an inflamed and sloughing condition in the abdominal wall.

Mr. H. F. WATERHOUSE said that appendicostomy would be in the future the operation in cases of ulcerative colitis and in most cases of mucous colitis.

Mr. KEETLEY in his reply, referred to the teaching of Sir William Macewen on the function of the appendix. Concerning the washing out of the colon he maintained that it was best done by means of appendicostomy, and he said that to leave the stump of an appendix in the peritoneal cavity was as dangerous a proceeding as imbedding the organ in the anterior abdominal wall.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Leptothrix Infection.—The Diagnosis and Treatment of Pancreatic Disease.

IN the account of the inaugural meeting of this society on Nov. 4th, which was published in the last issue of THE LANCET, we were obliged to hold over the reports of papers read by Mr. E. W. Scott Carmichael and by Dr. D. Chalmers Watson with the subsequent discussions.[1]

Mr. CARMICHAEL, who took for his subject "Leptothrix Infection: a Case of Pyæmia with Meningitis, and Notes of Two Similar Cases," said: "In April, 1906, in consultation with Dr. T. Thyne, I saw an infant, aged four months, who had suffered from gastro-intestinal symptoms for a fortnight. Two days previously the child began to suffer from abdominal pain, which suggested to Dr. Thyne the possibility of peritonitis. The abdomen was swollen, tympanitic, and rigid, the child presenting locally all the symptoms of general peritonitis. The general condition of the child, however, was not such as one would associate with a general peritonitis due to the more common pyogenic organisms. The abdomen was opened, and general peritonitis, evidently of some duration, was present. The pelvis was full of a somewhat serous pus, and there were dense adhesions between the coils of intestine. These were especially so around the cæcal region, so that no attempt was made to find the appendix. Multiple drainage was used for the pelvis and lumbar regions. The child made an uninterrupted recovery and was dismissed some weeks afterwards completely cured. An ischio-rectal abscess developed a month later but since then the child has been in good health. The pus from the abdominal cavity was submitted to bacteriological examination. Mr. Richard Muir reported that the infection was a mixed one but that the predominant organism was a leptothrix probably of intestinal origin. The interest of this case lay in the fact that the child was very young (four months) and recovered after an attack of generalised acute peritonitis. The child was never so seriously ill as might be expected in a case of generalised peritonitis and has since been in good health. Recently it has been my good fortune to meet with another case. I am indebted to Dr. James Ritchie and Dr. Stuart Macdonald for the pathological and bacteriological investigations of the case. A child, aged 18 months, was sent by Mr. J. T. Dickie to Dr. John Thomson's ward on May 6th, 1908. The child had been ailing for about ten days with gastro-intestinal symptoms. Two days before admission to hospital swelling appeared in the right lower limb. Dr. Thomson asked me to see the case with him. There was general œdema of the limb up to the lower third of the thigh. There was no redness or inflammation, except for a small area of about the size of a shilling in front of the external malleolus. The temperature was 104° F. The diagnosis lay between an acute osteo-periostitis of the tibia or fibula and a subcutaneous œdema of septic origin. The child, though ill, was not so bad as to lead one to suppose that there was disease of the bone, and the absence of redness and the general appearance of the limb were not characteristic of acute osteomyelitis. There was no localisation of the swelling. The knee- and ankle-joints were freely moveable without pain, although they participated in the œdema. Although the clinical symptoms were against osteomyelitis I did not feel justified in not exploring the bones of the leg. Incisions were made down to the bone over the tibia and fibula, but except for a general œdema of the subcutaneous tissues there was no evidence of more deep-seated inflammation. The reddened area was incised and a small pocket of pus was found under the common extensor tendons in front of, and independent of, the ankle-joint. This was examined bacteriologically by Dr. James Ritchie. The child's condition continued much the same for the next three days, the temperature remaining persistently about 103° F.; the general condition, however, was well maintained. Bier's treatment with the Sang-apparat was carried out during this period. Discharge from the right middle ear with bilateral swelling of both elbows was then noticed. The joints were markedly distended, but there was no redness or sign of inflammation or marked local rise of temperature. Both joints were drained and contained a large quantity of thin odourless and rather pale cream-coloured pus. These were again examined bacteriologically by Dr. Ritchie. The child's condition became distinctly worse. There was very little discharge from the joints, much less than is present in streptococcal or pneumococcal affections. The child lived for a week longer with continued high temperature. Two days before death there was some swelling of the cervical glands. Lumbar puncture was performed and a turbid fluid was drawn off which was examined bacteriologically. What struck me clinically about these cases was that the general condition of the child in each case was not gravely affected while the leptothrix infection was localised. In the case of the first child, though young, the recovery was complete. In the second child, though there was high temperature, the general condition remained fairly good until there was general systemic infection, as shown by the otitis media and the double elbow-joint affection. A corresponding infection of streptococcal or staphylococcal origin gives rise, as a rule, to more systemic derangement. The œdema of the leg was not associated with any redness. There was no evident active inflammatory change. The condition of the limb resembled much more that of œdema of cardiac or renal origin than that due to an inflammatory state. I have seen from time to time in the out-patient department children brought up with a similar œdema of the hand and forearm, unassociated with inflammatory change. In one case I made an incision and endeavoured to cultivate an organism but with negative result. On looking back on these cases I cannot but think that they may be of similar origin. The œdema often persists for a week or two without affecting the general condition of the patient to any marked degree and then gradually subsides. One has considered these often of a mild streptococcal nature without being able to grow such an organism. The want of local inflammatory reaction was markedly seen in the case of the elbow-joint swellings. It is unlikely that these had been overlooked for more than a day or two but the appearance much more resembled that of a tuberculous affection. It was not like an acute arthritis due to the more common pyogenic organisms. The pus was thin, odourless, and of a pale creamy colour. In the abdominal case it was thin and more serous, odourless, much more like the fluid of a pneumococcal condition. The organism if it is the cause of these conditions does not appear to be an acutely virulent one but can lead it is asserted that thrift among the working classes of that country has not thereby been promoted. Under the original Act of 1897, unless incapacity arising from accident lasted for two weeks no compensation could be claimed, but under the Act of 1906 claim for compensation is created by a single week's incapacity for work, and incapacity lasting for a week entitles to compensation from the date of the accident. It is not surprising to hear that this change has led to an increase of notified accidents; and while the paper stated that malingering by injured workmen was undoubtedly one of the causes of this increase, it was mainly due to this change in the recent Act which tempted workmen to extend the period of incapacity into the second week, with a view to create a claim for compensation. It was at the same time suggested that the increase of accidents might be due to some extent to decreased care in the supervision of work and machinery by employers who are relieved of responsibility for accidents by insurance. The fact was also alluded to that workmen in receipt of compensation and also of sick allowance from friendly societies not infrequently drew allowances exceeding the amount of their wages when at work. It was, however, admitted that workmen are not exempt from the widespread effects of neurasthenia, tending to delay physical and mental recovery after accidental injury. In the discussion which followed the reading of the paper the interesting question was raised whether liability to accident increased with the age of the workman, on which point opinions were much divided. Sir John Brunner, referring to statistics on the subject recorded at the works of Brunner, Mond, and Co., stated that these statistics showed that the comparative liability to accident declined in constant relation to the increase of steadiness due to increased age of the workman. While it has been generally believed that the Workmen's Compensation Act would lead to increased litigation it is satisfactory to hear that the fear of this result has not been realised.

---

[1] THE LANCET, Nov. 14th, p. 1447.

LIFTS AND HEALTH.

OWING to the increasing heights of new buildings the lift has become a necessity of modern life. The fatigue engendered by an ascent up the stairs to, say, the sixth floor of a hotel several times during the day would be intolerable, and without the lifts bedroom accommodation at such a level would appeal to nobody and would be so much space wasted. The same observations apply to offices in high buildings allocated to business purposes. The lift, in fact, was introduced to meet an enforced economy of space. Buildings could be pushed upwards but not outwards without encountering somebody else's property. Lifts, however, prove in the light of modern science to fulfil a much higher purpose than this. They bring within easy approach a healthier and purer environment. It is common knowledge that at the ordinary level of the highway we practically exist in a sediment of bacteria, amongst which pathogenic species may for certain be counted. Higher up bacteriological analysis gives a more satisfactory account. The refinements of bacteriology apart, chemistry also shows considerable impurities in the air at the ground level compared with the air, even at a small elevation, above. It follows that the air of buildings would be worst, both bacteriologically and chemically, on the ground floor, and then it would gradually show improvement as the floors above are reached until the cleanest air of all would be shown on the top floor. The lift may thus clearly take us out of the region of bacterial and other hurtful activities. Moreover, the health-giving properties of sunlight are more likely to be realised on the top floor than on any floor below. These facts render the policy of hotel-keepers and others perfectly illogical, which is that higher prices for rooms on the lower floors should be charged than for the rooms on the higher floors. It is, of course, in pure innocence that the hotel proprietor charges less for a healthier environment, and the visitor who has any regard for hygienic facts will not be slow to take advantage of this innocence. Doubtless there are those who reckon the ascending and descending of a building in a lift a source of inconvenience and delay or even of risk, but there are decided compensations, as modern science clearly teaches.

WATER ANALYSIS AND INSPECTION.

IN the *Queen's Medical Quarterly* Professor W. T. Connell of Queen's University, Kingston, Ontario, Canada, has called attention to a point insufficiently recognised by sanitary authorities, but often insisted upon in our columns, in the examination of water—the importance of inspecting the sources of supply. Samples of water are sent to a laboratory for analysis when inspection would at once reveal sources of contamination. Again, samples are sent to an analyst without sufficient data, such as situation of supply, proximity to sources of contamination, human or animal, and slope of the ground in the case of a well, to allow proper conclusions to be drawn. Inspection and analysis are complementary. Inspection reveals sources of contamination, while bacterial and chemical analysis reveals actual pollution, but in most cases cannot do more than suggest source of pollution. Professor Connell finds that too much dependence is often placed by local sanitary authorities on a few bacterial and chemical examinations. The sample passes a careful bacterial examination as it is of but small bulk and conditions of wind current and rainfall markedly affect its composition. An outbreak of disease afterwards occurs and sanitary inspection of the supply at once shows a patent source of pollution. Professor Connell does not desire to belittle analysis. Indeed, he looks upon it as the final court of appeal, but a sufficient number of tests must be made before a positive opinion can be given and inspection may make analysis unnecessary. On the other hand, a supply may pass inspection and be condemned by analysis, but further examination will then reveal the source of pollution. Sanitary water inspection is a matter for trained observers and such are not numerous in Canada. The need for them is shown by the prevalence of enteric fever in urban and rural communities throughout that country. Its development must cause increasing contamination of water supplies unless steps are taken to prevent it. Professor Connell thinks that some such legislation as the Rivers Pollution Act of Great Britain will be necessary. In the absence of sewage treatment and purification he thinks that the filtration of water has become important. He has studied mechanical sand filtration for some years. The water is filtered through sand under pressure after addition of a measured quantity of alum (varying with the quality of the water) to precipitate the chalk. The precipitate forms a scum on the surface which acts as a nidus for the usual water bacteria and also acts as an efficient filter, partly mechanically and partly biologically. Professor Connell reports unfavourably on samples of water from wells: 58 out of 102 were infected with the colon bacillus. Professor Shutt of the Central Experimental Station, Ottawa, has said that "the majority of farm well waters submitted to me for analysis are little better than cesspools." In rural districts pollution of wells usually arises from animal sources, such as manure and other stable refuse, and then the danger of acquiring disease, apart from diarrhœal affections, is slight. With pollution from human sources the danger is much greater. But it is not possible to distinguish colon bacilli of animal from those of human origin. Hence, again, the value who knew so much as to be beyond learning. He did not preach to them from any lofty pedestal of virtue. He had been slack in attendance and in the exhibition of work, partly from discouragement and partly from the usual causes which seemed to sap the energies of the seniors. But the responsibilities of office had made him reconsider the matter, and to decide to do his best to remedy the condition and to make others assist in doing so. The second cause of decay was the medical clubs—biological and clinical. They had come to stay and flourish, and long might they flourish. In proper circumstances they were distinctly helpful to the scientific life of Dublin, but they had exercised a pernicious influence in ways which it was easy to understand. There was no publication of work done by them. Men could discuss their cases in a free-and-easy way without committing themselves to statements which would be published. The clubs should be of special value as preparers for the Academy, and they should try to persuade members of the clubs of the great value of bringing their specimens and papers subsequently to the Academy. The third cause of the decay was the evil system of hospital appointments in Dublin, which had indeed existed at the foundation of the society. He alluded to the absence of proper apprenticeship for the profession. Men were often run into hospital appointments fresh from the schools without any training as an assistant or a registrar, or both, that they should have had. In some hospitals the assistant surgeon was merely a drudge to do the extern work instead of an assistant to a senior. In others he was at once put in charge of beds and given the responsibilities of a senior. Such a system resulted in immature surgeons who, from a consciousness of their own deficiencies, were afraid to speak in a place like the Academy; or it might result in over-confidence which would some time lead to a ludicrous mistake that would prevent them from entering into contest with others again. There were, however, he was glad to say, indications of improvement. Some hospitals now had real assistancies and registrarships and he had good hopes of them. The impetus to scientific zeal that must ensue from the establishment and endowment of the new university must also result in good work. He was, therefore, more hopeful than when he began to consider the question, and he would ask them all to endeavour to insure that the Academy would in the future not only rival the best work of the past but far surpass it, with lasting benefit to Irish surgery.

Mr. E. H. TAYLOR exhibited a woman who went to hospital for relief of Pain in the Left Shoulder. On examination a hard swelling was detected in the posterior triangle of the neck, which was diagnosed as a cervical rib. This was confirmed by a skiagraph, which showed a well-formed cervical rib on the left side and a smaller incomplete rib on the right. The patient did not present the nervous and vascular disturbances which were frequently found associated with the presence of cervical rib.—Dr. W. S. HAUGHTON said that in close on 8000 examinations with x rays he had only come across four similar cases.—Mr. A. J. M. BLANEY said he had shown some time ago a similar case, in which the whole of the forearm was blue, with pains shooting down to the fingers. The pulse was quite lost. The removal of the rib was easy; the result was a cessation of pain.—Mr. W. I. DE C WHEELER said it was remarkable that the symptoms in such cases seemed to come on in adult life.

Dr. HAUGHTON showed a boy, aged six years, suffering from Multiple Rickety Deformities, some of which had been treated by operation. On admission to the Orthopædic Hospital, amongst other deformities, he had considerable anterior curves on both tibiæ, double genu valgum, and severe curves of both radius and ulna of the left arm, limiting flexion and preventing pronation and supination. Skiagrams were shown demonstrating these conditions before and after treatment. Cuneiform osteotomy was first performed in the left tibia, the necessary wedge of bone to be removed being first accurately measured by placing the legs of a pair of compasses on the skiagram—one leg in the normal axis of the tibia, the other leg of compass along the axis of the lower end of the deflected portion of bone. The angle of deformity thus accurately measured was recorded by cutting a piece of aluminium to this angle. This formed a "sterilisable template," which when laid on the exposed surface of the tibia could be outlined by two cuts on the periosteum. By following these lines with a saw or chisel a wedge of bone would be removed the angle of which truly represented the "angle of deformity." The deformity was then forcibly reduced and apposition of the bones maintained in plaster-of-Paris. The double genu valgum was treated by "double condylotomy" at two sittings—"plaster-of-Paris" being applied in each—and the child was kept in bed for a prolonged period. Movements of the knee-joints were now good and the child, though not encouraged to walk much yet, could, nevertheless, walk with ease. The forearm Dr. Haughton proposed to treat also by osteotomy.—Mr. D. KENNEDY said that in children before four years of age he had frequently bent the bones into position with almost perfect results. The after-treatment of such cases had to be carried out for a lengthened period, otherwise relapse was bound to occur.—Mr. TAYLOR said he had always performed Macewen's supra-condyloid osteotomy which fulfilled the conditions of the case admirably.—The PRESIDENT commended Dr. Haughton's device for calculating the angle of deformity which would do away with the time lost in making repeated sections to get the bones to fit.—Dr. HAUGHTON, in reply, said his experience was that in cases where, in the dispensary, they thought they could obliterate the curves by straining movements the bones became so hard after six weeks of good feeding in the hospital that they could not be bent any more. In supra-condyloid osteotomy the angle of deformity was corrected but another deformity was produced. However, if the child was well fed and the limb was kept in plaster-of-Paris that method would give as good results as the other.

Mr. KENNEDY exhibited a patient on whom he performed the intra-scapulo-thoracic amputation for an extensive Injury of the Arm, due to a railway accident. The scapula was comminuted and the soft parts of the arm mangled and torn so high up that it was impossible to get covering for an amputation through the shoulder-joint. The operation was performed within two hours from the time of the accident. Mr. Kennedy attributed much importance to immediate operation in such cases.

Mr. LOUIS A. BYRNE exhibited a man, aged 21 years, who was admitted to Jervis-street Hospital on Saturday, Nov. 2nd, 1907, suffering from an Injury to his Head. The patient made the following statement. A short time previously he was "tricking" with a fellow workman and threw a dirty bag in his face; the other lost his temper, took up an iron bar, and struck him on the head. He fell to the ground; the ambulance was sent for, he was taken to hospital, and put to bed. On examination there was a slight swelling over the right parietal region, a very slight scratch; no other mark. His pupils were normal and responded to light. His senses were not impaired. The respirations were 20; there was no nausea or vomiting; the temperature was 98·4° F., and the pulse was 60. Finding the pulse so low Mr. Byrne decided to take him into the theatre and under an anæsthetic to dissect back the scalp and examine the skull, which he accordingly did, and found a gutter fracture extending about two and a half inches, the depression being most marked. He trephined the upper fracture at its anterior margin and elevated it but was unable to elevate the lower one. He then had to trephine the lower one in its posterior margin and successfully elevated it, but immediately very severe hæmorrhage took place which necessitated the plugging of the wound with iodoform gauze. He then covered the wound with gauze and had the patient at once removed to bed, where he made an uninterrupted recovery and was discharged on Jan. 4th, 1908. He returned to his work and has continued at it ever since and has not complained of any trouble.—Mr. TAYLOR said he thought that the hæmorrhage was meningeal. The probability was that until the bone was elevated the middle meningeal artery was compressed in some way, and when the bone was elevated the artery, which probably had been torn, started to bleed vigorously. In using a small trephine there was danger of wounding the artery.

Mr. GRAVES STOKER exhibited a woman whose arm he had amputated for Gangrene due to Acute Cellulitis. The patient received a small wound which became infected and gangrene set in two days after her confinement. She was in such an exhausted condition then that he did not consider operation advisable. The gangrene continued to spread for some days, but eventually some signs of a line of demarcation made their appearance. Amputation was performed on the tenth day after her confinement and she made satisfactory progress thereafter. Notwithstanding the virulence being sufficiently high. In the case of the fluid extracts of meat, which should contain from 50 to 75 per cent. of solids, several fell below the minimum figure. Some of these products cost more than a solid extract of meat, although they contain much more water. None of the samples of meat juice examined contained any appreciable amount of coagulable protein which should be present to the extent of not less than 35 per cent. of the nitrogenous bodies. It is possible to prepare a fresh meat juice by heating the meat to a temperature not exceeding 60° C. and expressing the juice. Samples prepared in this way in the laboratory contained practically one-half the nitrogenous bodies in a coagulable form, and in several cases a considerably larger proportion of the nitrogenous bodies were coagulable. The report includes a valuable discussion of the methods of analysis of meat products and a *précis* of published work on the nutritive values of gelatin and meat extracts and juices.

INEBRIATES' HOMES.

OUR Manchester correspondent writes: "Much regret was felt by those interested in the reformation of drunkards by the disappointing and discouraging report recently issued by the committee of the Langho Inebriates' Home. There was a note, too, of hopelessness, as if all efforts were useless, in the discussion at the meeting by the justices and others. The cures are reported to be no more than 20 per cent. Several letters on the question have appeared in the local papers; one from the lady in charge of a private home in Manchester, who takes a more hopeful view, giving two 'out of many instances that could be cited' where women 'sodden with drink' have recovered their self-control. In one case the woman earned her own living for years, and in the other, after being in the home from January, 1897, to March, 1898, returned home and 'has since acted the part of a true mother to her children whom formerly she neglected entirely.' This woman had been a habitual drunkard, spending a large part of her time in public-houses. Perhaps there is too great a tendency to take for granted that if a woman once gives way to drink she cannot be reclaimed, and so far as her family or society is concerned, is irretrievably lost. The honorary secretary of the Women's Union, Church of England Temperance Society, on the part of her committee, regrets the statements as to the impossibility of the reform of women inebriates deduced from the experience of the Government inebriates' reformatory at Langho. Rescue and preventive work have been carried on in the Manchester diocese for seven years, and instances can be cited where women drunkards have given up drinking and stood firm for five or six years. She believes that one great cause of the failure of the Government homes in the work of reform is that the cases are taken there too late. 'Under the existing law nearly all the women have so irreparably injured their brains through long-continued drinking that only life detention can be of any use.' As long as this is the case early treatment cannot be adopted, and the course advocated by another writer cannot be carried out—viz., that 'the care of the person who has begun to give way to habits of intemperance should be [illegible] only take in hand at the outset.' Another difficulty is the want of supervision and sympathetic guidance when these poor feeble-willed people emerge from gaol or home. The force of habit, and perhaps the acute return of the craving for drink, may undo in a moment any good that detention has seemed to effect; for the poor victim of this besetment may turn into the public-house, and unless she is on the black list can be at once served with drink. A woman from Rochdale, it is stated, was recently committed at Bacup for a month. The chief constable said it was her 181st known conviction and she had probably been convicted at least 200 times. In such cases as these, permanent detention seems the best thing for the women themselves and their families. It would be useless to send these cases to Langho unless they could be kept there for the term of their natural lives. Only last week a man was sent to prison for four months with hard labour for persistent neglect of his seven children and, it may also be said, of his wife. The children were ill-fed, badly clothed, dirty, of course, and the rooms they lived in 'reeked with filth.' His wife was too ill to be removed, but the children were taken to the workhouse and put under medical treatment. Since Oct. 10th the family had had parish [illegible] conditions it might have been thought th[illegible] for getting drunk would not be numerous, but on the 31st he contrived to get arrested for being drunk and fighting, and he was known to have been a drunkard for nine or ten years. Whether such a man is wilfully or involuntarily a drunkard he is a pest to society. What ought to be done with him? The injury he does to the State by being the father of—almost certainly—decadent children, injured still further by ill-treatment, ought to be prevented. But how? The solution that seems most promising to many is detention in a labour colony, where at least his keep ought to be earned, either permanently, or till there is good evidence of reformation."

THE POPE AS A "GOOD SAMARITAN."

THE "sacerdotal jubilee" of Pius X. has brought to the Vatican not only deputations and pilgrimages innumerable, charged with words of congratulation on the anniversary, but also messages, similarly inspired, by post and telegraph hardly less gratifying to the august Pontiff. Among these latter there is one which contains an incident thought worthy of a place in the "Vox Urbis," a monthly organ of the Vatican, written and published in the language of St. Augustine, or, the flow of its Latinity considered, of St. Jerome. The incident referred to must have relieved, in the Pope's mind, the monotony of the addresses and congratulatory letters, dealing as it does with the past, on which he has every right to dwell with satisfaction, and not on the present or the future, replete with the difficulties and dangers inseparable from "the head that wears a crown," still more from that which is pressed by a tiara. "Pius X. et Miles Austriacus," such is the title of the narrative to which the "Vox Urbis" draws the attention of its readers, and the tenor of which is as follows. In 1865, when the Venetian province was still a part of Austria, a soldier of the line, Johann Baier by name, during the autumn manœuvres, collapsed, footsore and weary, from his exertions, and was found lying in a ditch on the marching-route near the village of Tombolo. His condition was deplorable; heart failure seemed imminent, when there happened to pass by the priest of the parish, who gave him all the "first aid" that the "sagacité de cœur" could devise, refreshed him with food and drink and supplied him with the "sacro numismate," something more than the "two-pence" (δύο δηνάρια) given by a similar benefactor on a similar occasion. That priest—a "Good Samaritan" for the nonce—was Giuseppe Sarto, now in the Chair of St. Peter. Next year the same soldier, s[illegible] lines on the fatal field of Sadowa, was [illegible] id thereafter lived as a pensioner in [illegible] village of Litschen, where he kept a [illegible] years had elapsed when, readi[illegible] of Pius X., he thought that the Pontiff could be no other than the parish priest of Tombolo who had relieved him in his distress. Accordingly, he addressed the Holy Father in a modest letter, recalling the incident and asking if he were methods of treatment.—Mr. Henry Wilson and Dr. E. Vipont Brown described cases of Malignant Disease treated by Trypsin.—The following were Mr. Wilson's cases:—1. Lymphosarcoma affecting the cervical glands; first noticed June, 1906. After six months' treatment with hypodermic injections of trypsin and amylopsin the glands were much reduced in size and were now freely moveable. The patient was now in good health and able to earn his living. 2. Scirrhus of the breast. Excision (axilla being cleared out) Feb. 11th, 1906. Recurrence in cicatrix September, 1906. Multiple secondary growths appeared shortly after. There were acute pain, rapid wasting, and loss of strength. The patient was dependent on morphine. Trypsin treatment was commenced on Feb. 17th, 1908. In a month the patient was almost free from pain and did not require morphine; she slept well, the appetite returned, and she gained weight and strength. This improvement was maintained for five months; then, in consequence of discomfort caused by the injections, further treatment was refused and the patient was now going downhill. At no time during the treatment could any local improvement be detected.—Dr. Brown said that the first case which he had to mention was one of stricture (almost certainly malignant) of the œsophagus in a man aged 69 years. The treatment was commenced on May 25th and was followed by immediate improvement. Squire's preparations were used, a teaspoonful of their liquor pancreaticus fort being taken half an hour before each meal and one "sterilette" being injected every day. Three months after the commencement of the treatment a full-sized stomach tube passed into the stomach without any apparent resistance. Then the patient suffered from bronchitis, cystitis, and kidney trouble and the treatment was discontinued, with a consequent return of the stricture. He seems again to be responding to the treatment. The second case was one of carcinoma of the cervix, so severe as to be inoperable, in a woman, aged 56 years. The treatment was commenced on August 1st. In addition to the injections of Squire's "sterilettes" he also applied pledgets of wool soaked in Squire's lotio pancreaticus fort to the growth. Within a week it was evident that the growth was being dissolved away whilst the healthy tissues remained unaffected. Soon there was a large cavity to pack until the cervix was represented by a cavity continuous with the vagina, the examining finger passing directly to the internal os. There still remained much thickening around. The patient unfortunately was an alcoholic and drank herself almost to death during the treatment. She was still under care. There was no smell and very little pain.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this association was held on Nov. 5th, Dr. R. C. Buist being in the chair. — Mr. A. Don showed a patient upon whom he had operated for Abscess of the Liver and subsequently read notes on the case.—Dr. J. Mackie Whyte showed a young girl, aged nine years, with a chancre on the upper lip.—Dr. J. S. Y. Rogers showed a boy, aged 11 years, with well-marked and Complete Unilateral Hypertrophy of the Left Side, the head, face, arm, and leg, hard and soft parts, being involved in the condition.—Dr. G. F. Whyte showed a mother and child with Abnormal Thumbs. Several other members of the family had similar affections. X ray photographs were exhibited which showed the abnormality to consist of a long thumb, with three phalanges, as in a finger. —Mr. D. M. Greig showed a boy, aged 10½ years, with Neurofibromatosis. A large tumour had been removed from the back below the right scapula which was found to consist of neuro-fibromata. Scattered all over the body just under the skin were numerous elongated nodular masses which felt like atheromatous vessels, or "pieces of ipecacuanha root."—Professor A. M. Stalker exhibited the specimen of a Heart from a case of Slow Cardiac Death. The left auricle was filled with a hard striated clot firmly adherent to the walls, with a very narrow passage in the centre through which the blood passed. When first seen the patient, who had cerebral embolism, was at a very low ebb, and death appeared imminent, but he lingered on more dead than alive for several days. Professor Stalker also showed two specimens of Ulcer of the Stomach.—Dr. Buist exhibited a Four Months' Fœtus in which death had been caused by the umbilical cord passing under the right knee, then round the thigh and leg and thus constricting the part under the knee. He also exhibited an infant in whom, when born, the heart was found beating on the right side and there was dulness all over the chest. This was found post mortem to be caused by a diaphragmatic hernia, the whole contents of the abdomen with the exception of the liver and stomach being in the left side of the thorax.—Dr. Mackie Whyte read notes on a case of Aneurysm of the Descending Thoracic Aorta, which occurred in a man, aged 43 years, a baker by trade. For 12 weeks he had vomited about half an hour after food, this being followed by severe pain in the chest. He had lost flesh steadily and was very thin on admission. There were limited movement of the left side of the chest and dulness over the left lung behind from the mid-scapular region downwards, extending to the right border of the vertebral column. Over the whole left lung there were resonant and dull areas, and there was a striking absence of breath sounds and voice conduction. The heart was normal in size, there was an accentuated second sound in the aortic and pulmonary areas, there were no murmurs, the radial pulses were equal, and there was no thickening of the arterial wall. The pupils were regular. The condition remained unchanged for two months, except that the dulness increased towards the axilla and to the front of the chest. He lost weight steadily and died suddenly one morning. Post-mortem examination showed a large emphysematous right lung with old tuberculous nodule at the apex and a consolidated left lung with numerous small bronchiectatic cavities containing pus. The heart was normal; in the descending aorta there was a large irregular fusiform aneurysm with considerable secondary bulging which had ruptured into the anterior wall of the œsophagus four inches above the cardiac orifice of the stomach. The stomach contained a solid blood clot weighing 2¾ pounds.—Mr. Don read notes on a case of Intussusception of the Sigmoid caused by a Polypus. The patient, a woman aged 44 years, was admitted to the Dundee Royal Infirmary on Sept. 1st with prolapse of the bowel. On examination, the bowel was seen to protrude eight inches through the anus and at the apex was a polypoid mass. The lumen was patent and the bowel looked gangrenous. Chloroform was administered and partial reduction was made. As this was found not to be satisfactory the abdomen was opened and there was found to be an intussusception of the descending colon into the pelvic colon. This was reduced and a loop of bowel was sutured to the peritoneum and the skin, and the part with the tumour left outside, and two days later this was excised. On microscopic examination this was found to be an ordinary villous papilloma. The patient steadily improved and on Sept. 19th an attempt was made to close the opening. This proved to be difficult and tedious owing to the amount of the sigmoid which had previously been removed. On the night before the operation and also in the morning a hypodermic injection of one-quarter of a grain of morphine and 1-100th of a grain of hyoscine was given. This seemed to act well in preventing shock and lessening the quantity of chloroform required, only one ounce being used. The operation consisted in, first, a junction of the cut ends of the bowel by a lateral anastomosis and then a resection of the part of the bowel involved in the artificial anus. The patient made a satisfactory recovery. Mr. Don then read notes on a case of Abscess of the Liver upon which he had operated.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on Nov. 11th, Inspector-General R. Bentham, R.N. (retired), being in the chair.—Major C. G. Spencer, R.A.M.C., showed an officer, aged 43 years, who was convalescent after having suffered from a large single Tropical Abscess of the Liver which followed an attack of dysentery in February of this year. The abscess had been aspirated three times and the cavity injected with a 1 per cent. solution of quinine hydrobromate on each occasion. In all, 151 ounces of pus had been removed and 20 ounces of the solution injected. No living amœbæ could be found in the pus which was sterile on culture. The leucocyte count had been high throughout. The patient had gained more than 2 stones in weight and had recovered his normal health.—Captain L. W. Harrison, R.A.M.C., showed a gunner of the Royal Garrison Artillery who was suffering from kala-azar. The man had been stationed at Madras and had been brought into intimate contact with natives. The edge of the spleen extended three and a half inches to the right of, and three and a half inches below, the umbilicus. The temperature chart was shown and it illustrated the intermittent type of the pyrexia. The patient had marked leucopenia. The Leishman bodies had been recovered by the right lung of the subject many tuberculous nodules could be recognised as well as a large cavity. In fact, according to Dr. Severi's account, the condition of the body was much the same as that of a body which we inspected in 1901[1] and which had been preserved by MM. de Rechter by means of formaldehyde vapour. So far as we can judge by the descriptions supplied to us Cav. Chiarella's method seems both simple and efficacious.

A TELEGRAM from the Acting Governor of the Mauritius, received at the Colonial Office on Nov. 13th, states that for the week ended Nov. 12th there were 18 cases of plague and 11 deaths from the disease.

ROYAL SOCIETY OF MEDICINE.

DEBATE ON HEREDITY, WITH SPECIAL REFERENCE TO CANCER, TUBERCULOSIS, AND DISEASE OF THE NERVOUS SYSTEM.—(*Continued from p. 1469.*)

Professor W. BATESON (Cambridge) said he supposed that the object of inviting him to address that gathering of medical men was to say something of the results which had been obtained in the study of heredity by the application of experimental methods to animals and plants. The work which had been done in the matter had been almost entirely by following up the hints obtained from the work of Mendel. He would have no difficulty in showing that the conclusions to which Mendel came were applicable with considerable precision to the descent of disease or congenital deformity in man. The first principle was shown by crossing tall with short plants. Biologists knew that a plant or animal in the ordinary way was a double structure, having received a series of elements from its father and a series of elements also from its mother. The confusion people used to get into when they tried to trace out rules of heredity in animals and plants was due largely to the fact that they did not realise sufficiently that a plant or animal was a double structure. As a matter of clinical experience it was not found that the union of tall with short produced plants of a height intermediate, but a certain number of plants as tall as one parent and a certain number as short as the other parent. Mendel made the discovery that in all cases to which his rule applied when dissimilarities met in one individual there was a separation between the two elements, which might be represented diagrammatically by lines representing respectively the male and female cells: that was the phenomenon of segregation. Biologists had been accustomed to talk of dominants and recessives. With regard to the inheritance of disease, the consequence of the recombinations of those cells produced by hybrids were obviously that in some cases there would be a meeting of long to long and short to short, and in other cases of long females with short males, or long males with short females. It was known by experiment that the short plants bred pure, just as if they had never had a cross at all. They bred pure because they had none of the quality of tallness in them. The interest in the theory lay in the fact that it enabled one to make analyses of the composition of the animal or plant so far as Mendelian principles could be traced. The plant could be analysed into its component units. The animal must be thought of as a great number of things: height, colour, and other characteristics were separately transmitted. Many attempts had been made to form pedigrees of the descent of eye colour. It was impossible to define the various colours of eyes by using words; but the difference between dark and light eyes consisted in the fact whether there was or was not pigment in front of the iris. In the ordinary blue eye there was no pigment in front of the iris. When the pigment was there it could be transmitted, but when there was none the children of such people had none of it. With regard to deformities and disease he showed photographs of a case of brachydactylia, in which the adults had only two phalanges in the fingers and toes. That condition behaved like the character of tallness in a plant and became a dominant. The individual might be pure to that condition, in which case all his children must have it, or he could be impure to it, like the plant in the case of tall and short. In all cases where disease existed it was the smaller number which dominated. That was the general rule. In the case of the fingers the reduction from three to two was dominant, and it was found also in the case of the Manx cat's tail in which the vertebræ were packed together in an irregular fashion instead of being divided out. The Manx cat was an imperfect dominant. He also showed a pedigree of cataract, the infantile form, in which the condition was seen at, or soon after, birth. The affected could pass it on and again it became dominant. Another slide showed the pedigree of a female with keratosis palmæ, in which condition the skin of the hands was abnormally thick. It behaved with one doubtful exception as a dominant and it was passed on through the affected. With regard to tuberculosis and cancer, biologists had no evidence which was direct, but a fact which had an indirect bearing of importance was that tuberculosis was an invasion by an infecting organism and it was not improbable that cancer might have a similar causation. Biologists could not trace on ordinary naturalist lines any ordinary heredity about those diseases. The case regarding nervous diseases was different. Another pedigree was from epidermolysis bullosa. There were exceptions in that but generally the persons who had the condition passed it on. A chart was also shown of retinitis pigmentosa in which the condition was passed on by those who had it. Dislocation of the lens, as worked out by Mr. A. Stanford Morton, was another condition which was transmitted. He also showed the largest pedigree of a human malformation or disease which had yet been worked out. It related to a condition known as night-blindness. It referred to a family which was investigated in the South of France in 1828. It was traced back to a person in the seventeenth century, who came into the south of France with the condition and all those who had it could be traced in a direct line. Human descent was most difficult to follow and anyone who had had experience of it could bear out what Sir William Gowers had said. There were departures from simple Mendelian rules which ought to be dealt with eventually. It could not be hoped that insanity would be regularly traced, chiefly because it depended in many instances on environmental influences and upon opportunity for development. The numbers arrived at in an investigation were 117 affected and 99 unaffected, which was as near equality as could be expected from the rough medical records available. With regard to recessives, that meant generations in which something was absent. The albino was a case in point: it lacked the normal amount of pigment. The rule for recessives was the reverse of that applying to dominants. With regard to the descent of sex-limited conditions, the best known of those were pseudo-hypertrophic muscular paralysis, hæmophilia, and colour-blindness. Pseudo-hypertrophic paralysis and hæmophilia were both so serious that it was impossible to hope to get pedigrees of the descendants of affected persons in sufficient quantity to enable an investigation to be made of them. But colour-blindness was not seriously damaging to the chances of life and therefore could be investigated. He thought they had been able to produce a scheme of descent which represented the facts so closely that there could be no reasonable doubt that it was very nearly the actual scheme In the case of females the female would not be colour-blind unless she had two doses of colour-blindness; she must be pure in colour-blindness. But the male might show colour-blindness if he had only one dose of it. And that was represented in the scheme which he showed. When the female had only one dose she did not show it, although she might transmit it to her offspring. It meant that colour-blindness was dominant in males and recessive in females. Night-blindness might have been thought to be due to the absence of something in the body, but it was known that it was a condition due to the presence of something, possibly something the effect of which was comparable to nicotine poisoning. In some of the cases of disease many of the subjects had not lived long enough to show whether they could reproduce their species, and, if so, what the result would be.

Dr. G. H. SAVAGE said that his contribution to the debate would consist in bringing forward the impressions formed by a long clinical experience and he would do no more than and Dr. J. Murray Bligh showed: 1. Carcinoma of the Ovary removed from a girl, aged 14 years. There was a history of wasting. The tumour occupied the greater part of the abdominal cavity and weighed 6 pounds. 2. Adenoma of the Tongue from a woman, aged 39 years. It was a sessile tumour situated at the base of the tongue. Large veins coursed over its surface and these had been responsible for severe hæmorrhage. 3. Naso-pharyngeal Fibroma removed from a youth, aged 19 years. It occupied the whole of the naso-pharynx and right nasal cavity. Breathing and swallowing were seriously obstructed and severe hæmorrhage had occurred. The growth was fibromatous, containing large blood-vessels.—Mr. D. Douglas-Crawford and Dr. H. Leith Murray showed: 1. Adenoma of the Tongue removed from a baby three days old. The tumour grew from the base of the tongue, was pedunculated, and gave rise to serious attacks of spasmodic dyspnœa. The tumour very closely resembled the gland tissue of the breast. 2. Adenoma of the Wall of the Maxillary Antrum removed from a woman 18 months ago. She then had a history of trouble for five years. The tumour had recently recurred; there was now proptosis but no invasion of the cheek or glands. The tumour showed apparently a simple cubical-celled adenoma.—Professor B. Moore gave a demonstration of Oxydases in Relation to Scorbutic and Antiscorbutic Foods. He showed by tests that these bodies were absent in foods showing scorbutic tendencies, were present in unboiled milk, while absent in boiled milk. Fresh vegetable juices contained them, but boiling or drying destroyed them. Prolonged boiling was necessary in the case of the potato. He showed a colloidal suspension containing oxydases obtained from the potato by precipitation with 20 per cent. alcohol.—Dr. T. R. Bradshaw did not consider that it was proved that scurvy was due to the absence of the antiscorbutic properties from the food. He considered it would be unwise to discourage the boiling of milk.

---

[1] THE LANCET, Nov. 9th, 1901, p. 1279.

HUNTERIAN SOCIETY.—A meeting was held on Nov. 11th, Dr. A. T. Davies, the President, being in the chair.—Dr. Purves Stewart showed a large Tumour of the Pituitary Body, which had caused bilateral temporal hemiopia, drowsiness, and voracious appetite, a group of symptoms which he regarded as typical of tumours in this position.—Mr. H. M. Rigby showed a Hair Ball which he had removed from the stomach; it formed a complete cast of the viscus.—Dr. Russell Andrews showed a Large Fibroid Tumour which he had removed from the uterus during pregnancy without producing abortion; also some specimens illustrating Wertheim's method of performing hysterectomy for malignant disease of the cervix of the uterus.—Dr. W. Langdon Brown showed a Series of Intracranial Vascular Lesions, including two ruptured aneurysms of the anterior communicating artery, red softening following cerebral embolism in mitral stenosis, syphilitic thrombosis of the vertebral artery, and a lenticulo-striate hæmorrhage in a patient with infective endocarditis, presenting unusual symptoms. He spoke of the assistance that observation of the blood pressure had been in the diagnosis of some of these cases.—Dr. O. K. Williamson showed a Hypertrophied Heart from a case in which the blood pressure had been persistently high; the splanchnic vessels were more diseased than the thoracic aorta.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on Nov. 11th, Professor William Stephenson, the President, being in the chair.—The following office-bearers were elected for the ensuing session:—President: Professor Stephenson. Vice-Presidents: (senior) Dr. F. W. N. Haultain, and (junior) Dr. A. H. Freeland Barbour. Treasurer: Dr. W. Craig. Secretaries: Dr. G. F. Barbour Simpson and Dr. Angus Macdonald. Librarian: Dr. Haultain. Editor of Transactions: Dr. W. Macrae Taylor. Members of Council: Dr. J. Lamond Lackie, Dr. D. J. Graham, Dr. A. T. Sloan, Dr. R. P. Ranken Lyle, Dr. J. W. Ballantyne, Dr. W. H. Miller, Dr. A. M. Easterbrook, and Dr. W. E. Frost.—Professor Stephenson gave his presidential address on a Historical Study of our Forefathers in Midwifery, discussing the views on various obstetric subjects held by William Smellie, William Hunter, Thomas Denman, Professor Hamilton (senior), Dr. John Binns of Glasgow, Dr. Ramsbotham (senior), and others.

Reviews and Notices of Books.

Lumley's Public Health Acts Annotated, with Appendices containing the Various Incorporated Statutes and Orders of the Local Government Board. Seventh edition, in two volumes. By ALEXANDER MACMORRAN, K.C., JOSHUA SCHOLEFIELD, and S. G. LUSHINGTON. London: Butterworth and Co. and Shaw and Sons. 1908. Vol. I., 1–1220 pp.; Vol. II., 1251–2444 pp. + Index 224 pp. Price £3 17*s.* 6*d.* for two volumes.

WHEN a standard work of this importance and magnitude reaches its seventh edition it has already established its claim as judged by the conditions of supply and demand to be regarded as practically without a rival, and whatever may have been the case formerly the amount of information which the two volumes here in question contain is greater than any other two volumes on the same subject with which we are acquainted. Clearly the next edition must run to three volumes if the work is to be handled easily.

Since the last edition of the work, some six years ago, Parliament has passed many public health statutes and the Local Government Board has issued many circulars on the subject, and all these are included, annotated and commented upon in the present issue. Moreover, the value of this edition is very materially enhanced by the inclusion of notes on the practice of the Local Government Board, as well as notes relating to the construction to be placed upon difficult provisions of the statutes. As the authors observe it is in many cases the "practice of the Board" which constitutes the law. The opinions of the Board are also of value in that they are the views of experts who have spent their life in this work, while in some instances such opinions are those of the law officers of the Crown. The work is admirably arranged with a capital table of contents at the beginning and a clear and helpful index at the end, considerations of no small importance in dealing with a treatise of this magnitude.

Vol. I. contains the Public Health Act, 1875, together with other measures more particularly associated with it, while Vol. II. contains in the first part (Appendix I.) numerous other Acts relative to municipal work and dating from the Knackers Act of 1786 to the Notification of Births Act and the Small Holdings and Allotments Act of 1907. The second part (Appendix II.) embodies circulars, forms, and regulations of the Local Government Board as well as certain orders of the Home Office and the Board of Agriculture. It is a little puzzling to find that Vol. I. ends at p. 1220 and that Vol. II. begins at p. 1251.

Although this work is intended primarily for, and is used mainly by, clerks to local authorities, barristers, and others of the legal profession, and a copy is probably to be found of one or another of the editions in practically every office of a local authority, there can be no doubt that its possession will prove a pillar of strength to all those medical officers of health who wish to understand without much effort the general provisions of any public health statute and to learn the decisions which have been given with regard to them.

The Natural History of Cancer, with Special Reference to its Causation and Prevention. By W. ROGER WILLIAMS, F.R.C.S. Eng. London: W. Heinemann. 1908. Pp. 519. Price 21*s.*

THERE has never been a time in the history of medicine when more books were published on cancer than the present, and it may also be truly said that nowadays the divergencies of opinion as to the cause of malignant disease are greater than ever. From the extent and duration of his researches into various phases and questions of cancer Mr. Williams ha produced by the virus of syphilis. Another subject on which he hoped later to give precise details was in regard to tuberculosis. He believed tuberculosis was not acquired in asylums. Patients in those institutions were of low vitality and they developed tuberculosis because of that. The disease got rid of many of the unfit, especially amongst cases of insanity. For the first three or four decades there were records of more than 2000 necropsies and there were certain types of insanity the subjects of which were especially liable to tuberculosis: especially adolescent insanity, melancholia, and the hereditary forms of mental disturbance. He believed that in those people there was a favourable soil which led to the easy development of the tuberculous organism. The incidence of tubercle at the same age inside asylums was from 15 to 20 times as great as outside asylums. Investigations on the air-shafts, &c., in asylums showed that the air was not impure there, and the nurses and attendants who were always in the asylums did not develop the disease except with distinct rarity. A very interesting point was that he had never found a case of tuberculous meningitis among the enormous number of cases he had seen. With regard to alcohol, he agreed it was a most important exciting cause of insanity, but among 2000 necropsies which he had made at Claybury he had only found cirrhosis of the liver with ascites in one, and that was Jane Cakebread, who was convicted 400 times before it was found she was incapable of taking care of herself. If it was such an important cause it did not show itself in any very marked degree in the organs. But the potential lunatic was readily acted upon by alcohol, and the subject of it was brought to the asylum earlier than he otherwise would have been.

The discussion was then adjourned.

At the adjourned meeting on Nov. 18th

Dr. CHARLES A. MERCIER said that he proposed to point out some of the fallacies with which the subject was beset and to indicate some of the precautions that might be taken to avoid them. The usual mode of determining the existence of a hereditary propensity to a disease was to ascertain whether there were in the parentage or ancestry or among the near relatives of the deceased person instances of the same disease; if such instances were found it was concluded that the disease was derived by inheritance. The most obvious trap was in the application of the method to diseases of frequent occurrence. Supposing a disease so common that it affected 19-20ths of the population, then nine out of every ten persons would have both parents affected by it and only one person in 360 would have both parents free from the disease. Such a large percentage of apparently diseased persons would justify, according to the method in use, the conclusion that the disease was certainly hereditary, and thus they would arrive at the conclusion that a common cold was a hereditary disease. It was argued that insanity was a hereditary disease because persons who were insane were frequent in the families of the insane, but until very recently no attempt had been made to ascertain whether such persons were not as frequent in the families of the sane. The various manifestations of nervous instability were so common that it was unjustifiable to draw from their frequency in the families of the sane any inference as to the heritability of insanity. He (Dr. Mercier) was impressed with the number of insane persons (not including general paralytics) in whose families exhaustive search failed to discover any insane relative within a reasonable degree of consanguinity; he was more impressed by the number of sane and normal persons who possessed near relatives that were either insane or subject to allied nervous disorders. When a comparatively rare disease such as hæmophilia was found to exist in the parents or near relatives of the diseased person, such a distribution of the disease was usually regarded as conclusive proof that the disease was hereditary; that inference, however, was quite unwarrantable and was usually shown to be so when the cause of the disease was discovered. A disease might be limited to a certain family without heredity having anything to do with the limitation, it was not justifiable to conclude that it was heritable merely because it exhibited family limitations. If it was established beyond question that insanity fell with special virulence upon certain families and left unaffected other families whose circumstances were the same, and if it could be established that the members of the families so affected had certain stigmata, still it was not justifiable to draw any conclusive presumption that insanity was heritable; all that they were justified in concluding was that it was probable that inheritance played a part in its production; something contributory to the disease might be inherited in such cases, but it did not follow that what was inherited was the disease itself; it might be a special vulnerability of the tissues or a special quality of blood which rendered the person so inheriting unable to resist the attacks of the noxious agent which was the true cause of the disease. For these reasons he (Dr. Mercier) believed that they were too apt to talk a little over-glibly about the inheritance of diseases. Supposing, however, that they had guarded themselves against all sources of fallacy and were justified in concluding that a disease was indisputably inherited, then they had to estimate the significance of that conclusion, and the significance for the members of the family in which the disease occurred would differ according to whether the disease was merely a variation or whether it was a true mutation. If it was a mere variation—that is to say, a mere pronounced deficiency or excess of some quality which generally varied in quantity, then it had little significance as a racial peculiarity. Such variations had a strong tendency to return to the average. When, however, the quality was not a mere exaggeration of a frequent variation but a true mutation—that is to say, a quality appearing *de novo* in the race—then it would breed true. Whenever a disease was distributed in successive generations in accordance with Mendelian laws it could not be doubted that the disease was truly inherited; but they were not entitled to assume the converse and to limit the inheritance of disease to those instances in which the numerical proportions required by the laws of Mendel were strictly observed. It was probable that there were disturbing factors which interfered with strict numerical accuracy, and it was manifest that the number of offspring of any one pair of human beings was too small to allow the laws of Mendel to be asserted completely. The Mendelian laws were never *strictly* true except in the long run—that is to say, when applied to an infinite series—but the series never was infinite, the run was never long, and in the human race it was a very short run; therefore, the laws of Mendel never could be strictly true except by accident, though they always tended towards truth. In conclusion, Dr. Mercier said that there had been no attempt made to estimate the number of the sane members of any family and the insane members, so as to compare the sane and the insane numerically. The compilation of the statistics of inheritance which appeared in the reports of the Commissioners in Lunacy was a waste of time and labour. The statistics were of no value at all for any practical or scientific purpose. As far as his (Dr. Mercier's) own observations of the family history of the insane went, they seemed to show that in some families the insane members were distributed approximately in accordance with Mendelian laws and in some they were not; in some instances insanity seemed to appear *de novo* as a mutation, in others it was clearly a variation.

The discussion was continued by Professor KARL PEARSON.

Dr. ARTHUR LATHAM then opened the discussion on Heredity in Tuberculosis, which will be found at p. 1512 of this issue. This was discussed by Dr. J. E. SQUIRE, and a report of his speech and of Professor KARL PEARSON'S speech will be published in the next issue of THE LANCET.

Dr. E. F. BASHFORD opened the discussion on *Heredity in Cancer*, and his paper is printed at p. 1508 of this issue.

The debate was then adjourned.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Nov. 12th, Mr. HENRY MORRIS, the President, being in the chair.

In accordance with the report of the Court of Examiners it was resolved to issue diplomas of Membership to 91 successful candidates.

A letter was read from Mr. G. H. Makins resigning his seat

An important new article on Nephritis by Professor J. Rose Bradford takes the place of the article in the former edition on "Diseases of the Kidney Characterised by Albuminuria," by Dr. W. H. Dickinson. Professor Bradford discusses the condition known as "physiological albuminuria"—that is to say, in a "large but variable number of persons apparently healthy, the urine is found to contain protein matter in small quantities." This form of albuminuria has received considerable attention, and we agree with Professor Bradford when he says, "It is extremely doubtful, however, whether all such cases of albuminuria should be called 'physiological.'" It is quite possible that in some of the cases no serious kidney lesion is present, yet, on the other hand, such kidneys cannot with certainty be considered quite normal. The subject is of great importance in connexion with life assurance, and it is desirable that some statistics should be forthcoming as to the future history of those individuals who exhibit "physiological" albuminuria in young adult life. Other diseases of the kidney which are on the border-line between medicine and surgery are described by Mr. Henry Morris who has added a section on Malformations and Diseases of the Ureter. His remarks on renal calculus are particularly worthy of note.

We once more congratulate the editors on the success of their labours. The present volume is a valuable addition to the "System of Medicine." It contains much new matter and will serve as a most excellent work of reference.

A Text-book of the Principles of Animal Histology. By ULRIC DAHLGREN, M.S., of Princeton University; and WILLIAM A. KEPNER, A.B., of the University of Virginia. New York: The Macmillan Co. 1908. Pp. 515. Price 16*s.* net.

THIS work covers the general field of histology and is not restricted in the main to human and mammalian forms. It is intended to teach principles and deals with histology as a pure science. Here and there fundamental facts are illustrated by reference to the vegetable kingdom. Having regard to the fact that it deals with comparative histology it may be compared with Schneider's "Lerbuch der Vergleichenden Histologie der Thiere," although the arrangement is quite different in the well-known German work. The order of description follows a functional rather than a morphological sequence. After elementary chapters on protoplasm, the cell, and epithelium, we come to the supporting tissues, tissues of motion, electric tissues and those that produce light and heat, the circulatory tissues, and so on. There are a freshness and freedom of treatment of the subject which make the work peculiarly interesting to the reader who has a moderate knowledge of zoology, while the functional aspect of the tissues and organs described is prominently set forth. The amplification of body surface obtained by the corrugation, evagination, and invagination of surface is illustrated by excellent diagrams.

On p. 77 Cohnheim's fields are given as "Conheim's." The authors regard Engelmann's theory as so far the best theoretical explanation of the motion of the fibrillated muscle cell. The histogenesis of muscle is traced upwards in its evolution from the Medusa, and almost every group of animals is drawn upon to illustrate the structure and development of the motor tissues. The chapter on Tissues of Light-production is particularly interesting and includes a description of those all too little known mechanisms for the production and reflection of light in the cephalopods and the pholas. The importance of surface as a factor in the operations of the animal body is again insisted on and well illustrated in the chapter on circulation.

The chapter on the blood itself is short but suggestive. It does not give detailed descriptions of the leucocytes and their importance in health and disease. The authors speak of the nerve cells as organs of perception, conduction, and stimulation, the term "perception" being used in the sense of "perceiving or being stimulated by the outer conditions directly or indirectly through the stimulus of another nerve cell, cell product, or foreign substance." Bold, vigorous sketches are given of the varieties of nerve cells and also of the tissues associated with touch and equilibration. A good and readable account is presented of the eyes and other sense organs in invertebrates as well as vertebrates, which makes the chapter on the sense organs particularly interesting. Even the gas-secreting tissues are dealt with pretty fully, such as the float of Physalia, or Portuguese man-of-war, and the "gas secretion" of the teleost fishes. To each chapter some reference to the literature is added. The "technic," however, is given in "general outline."

We have said enough to show how interesting the whole work is in its all-round survey of animal histology in its wide sense. The work will prove eminently useful to the zoologist, but in it the physiologist and comparative anatomist will find much to excite thought, and any student who masters its contents will have laid a broad basis for future study of morphology, embryology, and the more strictly medical sciences. To this end the authors have chosen the functional rather than the embryological methods in developing their account of "Animal Histology." The illustrations—470 in all—are admirable, clear, bold, and effective. We have had much pleasure in perusing the book and cordially wish it the success which it deserves.

Clinical Bacteriology and Hæmatology for Practitioners. By W. D'ESTE EMERY, M.D., B.Sc. Lond., Clinical Pathologist to King's College Hospital and Pathologist to the Children's Hospital, Paddington Green, &c. Third edition. London: H. K. Lewis. 1908. Pp. 252. Price 7*s.* 6*d.* net.

THE first and second editions of this book were reviewed by us at length and in terms of warm approval when they appeared, and we are glad to see that a third edition has been called for in so short a time. Since the book has been very slightly modified the present edition requires no detailed comment. The description of the methods used for the collection of blood for bacteriological examination is somewhat fuller and certain points of detail criticised adversely in the review of the second edition have been modified and improved. The method of lumbar puncture is also given with more detail and with additional illustrations. The author finds that the examination of the cerebro-spinal fluid is of considerable use in the diagnosis of uræmia. A description of the methods used for making bacterial vaccines forms one of the chief additions to the book. Amongst the various means employed for the diagnosis of enteric fever no mention is made of the isolation of the bacillus typhosus by culture, though this plan seems to be of increasing importance. The author still holds that the presence of Hofmann's bacillus in the throat justifies the diagnosis of diphtheria. A method for the examination of pleuritic and other exudations for the bacillus tuberculosis and Leishman's method for staining the spirochæta pallida have been added to the appendix.

The typography and paper of the book have not improved. This work gives a very concise and accurate account of the subjects of which it treats and cannot fail to be of value to any practitioner who desires to carry out such methods of investigation as are described. It further enables him to select the right materials for examination and to interpret intelligently the results which are obtained by himself or the reports which are furnished by those to whom he has submitted the materials for investigation.

the county of Durham, was the originator of the lifeboat movement and chairman of the first committee.

Ruthin.—Mr. Thomas Owen Jones, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., the mayor of Ruthin, received his medical education at Anderson's College, Glasgow, and qualified in 1894. He obtained the appointment of medical officer of health of the Ruthin rural district in 1898, when he went to reside in the district. He is a Fellow of the Royal Institute of Public Health, deputy medical officer to H.M. prison and to Ruthin Union, inspector of school children, and lecturer and examiner to St. John Ambulance Association. For six years he was a member of the Ruthin town council but retired from active work on the council about three years ago.

Welshpool.—Mr. Richard David Thomas, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., who has been re-elected the mayor of Welshpool, is a native of Cemmes Bay, Anglesea, and has been resident in Welshpool for more than 18 years. He is a county district coroner, Poor-law medical officer and public vaccinator for Forden and Llanfyllin unions, medical officer of health of the Forden district, and medical inspector of school children. He first entered the town council in 1898 and has since been returned twice. In all that concerns the health of the borough he takes a most active interest.

NOTE.—By an error on the part of a correspondent we announced in our last issue that Dr. J. R. Hughes of Denbigh had been elected mayor of that borough.

MEDICINE AND THE LAW.

Prosecution for Practising under a False Description.

ON Nov. 5th before Sir Albert de Rutzen, at Bow-street police court, William Henry Tucker, *alias* John Dale Tucker, 58, was charged on a warrant with "falsely using the description of a Bachelor of Medicine and with acting as a doctor without being duly qualified." On Sept. 28th last the prisoner called upon Dr. J. Field Hall, managing director of Messrs. Field Hall, Limited, medical transfer agents, Strand, and stated that he was a medical practitioner and that he wished to dispose of his practice which he had been carrying on in Hackney. He was handed a printed form and this he returned duly filled up on the following day. His name then appeared as William Tucker, M.B. The premium which he asked for his practice was £160, which included the furniture. The reason which he gave for wishing to dispose of his practice was that he intended to go abroad. There were two William Tuckers on the Medical Register, but one was William Eldon Tucker and the other William Hancock Tucker. In 1906 the prisoner was convicted at Warwick Assizes of forging a death certificate in the name of William Eldon Tucker and sentenced to three years' penal servitude. At the trial he admitted that that was not his name. The magistrate said that he would not take the prisoner's conviction at Warwick Assizes into account. He imposed a penalty of £15 with £5 5*s.* costs. The practice of the healing art has long obtained legal sanction and recognition in this country. Practitioners were formerly divided into three main branches, known respectively as physicians, surgeons or barber chirurgeons, and apothecaries, whose functions and status were quite distinct, who were governed by different charters and statutes, and pursued their callings independently of, and sometimes in antagonism to, one another. Besides the above, there have always been, as there are still, persons who attended to human ailments without having any legally recognised qualification for doing so. The union of all qualified persons and their recognition as members of one profession are modern. By a statute passed in the year 1511 (3 Hen. 8. c. 11) no person was permitted to take upon him to exercise and occupy as a physician and surgeon until he had been examined and approved for that calling. The examination was in those days conducted under the sanction of, and the approval obtained from, the bishop of the diocese. Physicians obtained a charter of incorporation in the year 1518, and in 1522 their College got the right of examining and approving persons to practise physic concurrently with graduates of the Universities of Oxford and Cambridge. The bishop's licence was thus superseded (14 & 15 Hen. 8, c. 5). The College was also empowered to exercise control and supervision over all dealers in drugs. Surgery was originally practised by barbers. In the City of London the barbers obtained a charter of incorporation from Edward IV. in the year 1461. Many other skilled surgeons were, however, in practice, and in the year 1540 they and the barbers were incorporated and were given the exclusive right to practise surgery within the City of London and its suburbs (32 Hen. 8, c. 42). Under the title of "the mystery and commonalty of barbers and surgeons of London," the physicians and barber-surgeons seem to have attempted to monopolise all treatment of disease to their own profit, for in the year 1542 (34 & 35 Hen. 8, c. 9) an Act was passed declaring that it shall be lawful for any subject of the King "having knowledge and experience of the nature of herbs, roots, and waters, or the operation of the same, to practise, use, and minister in and to any *outward* disorder, any herbs, ointments, bettes, pultess, and complaisters, according to their cunning, or drinks for the stone, strangury, or agues, without suit, vexation, trouble, penalty, or loss of their goods." The company obtained a further charter in the year 1629 (5 Car. 1), giving it the right to examine and approve all persons who wished to practise surgery in London and Westminster, and empowering persons so approved to practise anywhere in England. In the year 1745 by Statute 18 Geo. 2, c. 15, the barbers and surgeons were separated into two companies. All the above liberties and privileges were transferred to the new Company of the Art and Science of Surgeons of London, who were empowered to make by-laws, &c., for their own regulation, ordinance, and government, and to examine candidates and authorising those who passed successfully to practise the art and science of surgery throughout His Majesty's dominions. It has been suggested that the above Acts, or at any rate the older ones, are obsolete. The Court of Appeal, however, in 1885 did not adopt the suggestion, though it did not expressly overrule it (Davies *v.* Makuna, 29 Ch D. 596). There have since that time been several general Statute Laws Revision Acts; but the above Acts, though amended in some minor points, remain on the list of statutes in force. In the year 1618 James I. granted a charter of incorporation to the apothecaries of London by virtue of which they practised their art and mysteries and enjoyed special rights and privileges for a period of two centuries. The charter was superseded in the year 1815 by the Apothecaries Act (55 Geo. 3, c. 194). By it the Master, Wardens, and Society of Apothecaries were empowered to regulate the conduct of members of their craft throughout England and Wales. Apothecaries are distinct from chemists in that they may administer medicines, while chemists may only prepare, dispense, and sell them. If a chemist prescribes medicine to his customers, as well as makes it up and sells it, he renders himself liable to a penalty (Apothecaries Co. *v.* Nottingham, 34 L.T. 76). The union of the different branches of the medical profession under one governing body was effected in the year 1858 by the Medical Act (21 & 22 Vict. c. 90). The original Act was amended in 1859 (22 Vict. c. 21), 1860 (23 & 24 Vict. c. 7), 1876 (39 & 40 Vict c. 40 and c. 41), and in 1886 (49 & 50 Vict. c. 48) These Acts are to be read together and are known as the Medical Acts. The Privy Council has now a general power of supervision over the General Medical Council. If at any time it appears to the former that the General Medical Council has failed to exercise any power or to perform any duty vested in or imposed on it by the Acts, it may notify its opinion of the same, and if the General Medical Council fails to comply with any directions of the Privy Council relating to such notification the Privy Council may itself give effect to its directions (Act of 1886, s. 19) Prior to 1887 the various constituents of the General Medical Council each granted their own diplomas, entitling their holders to practise in some one or more departments of medicine—e.g., as apothecaries or surgeons. More than one diploma was requisite for a man who was desirous of practising generally. Since June, 1887, no person may be registered unless he has passed a qualifying examination sufficient to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery (Act of 1886, ss. 2 and 3). Any person wilfully and falsely pretending to be, or taking or using the names or titles of, a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner, or apothecary, or any name, title, addition, or description implying that he is a

THE LANCET.

LONDON: SATURDAY, NOVEMBER 21, 1908.

The Appropriation of Sources of Water-Supply: a National Problem.

THE steady augmentation of our population and the growing desire for cleanliness, comfort, and even luxury are leading in every direction to an increasing demand for water not only for drinking purposes but also for baths and the cleansing of streets. The question, too, of street-watering is assuming vast proportions in consequence of the rural exodus and the growth of towns which results therefrom, while the substitution of the water-carriage system of excrement disposal for that of storage in privies, pans, and cesspools which still obtains so largely in our midland and northern towns is likely in the near future to make a very material addition to the drain upon our existing sources of water-supply. At the present time these demands are met in a somewhat haphazard fashion. Municipalities and water companies introduce Bills into Parliament which, sometimes after very scant consideration and by means of throwing a sop here and there to interested communities and persons, are allowed to reach the statute book, and the natural sources of one part of the country are freely tapped for the supply of towns far removed from such sources. Illustrations of what may be termed this predatory instinct are furnished by the cases of Birmingham and Liverpool as regards our Welsh sources of supply and by the case of Manchester as regards the English lakes. Gradually and almost unconsciously our upland water-supplies in the shape of natural or artificial lakes and the upper reaches of our rivers are being appropriated without any very clear idea as to the manner in which the demands of the future are to be met, and in the meantime numerous centres of population are left unsupplied and unconsidered. But this is only part of the story. Not only are our lake and river supplies being taken up, but also, and in a way more stealthily because less apparently, our underground water. Wells are sunk by public or private bodies which tap the underground reservoirs of supply without sufficient regard as to the manner in which the level, hardness, or salinity of the subterranean lake will be affected by the pumping operations. Numerous instances could be furnished of these conditions and of the manner in which some waters, such, for example, as those of the chalk in parts of Essex, have had their salinity increased as the water level descends.

A useful illustration of the difficulties referred to is furnished by the annual report of Dr. HENRY HANDFORD, the county medical officer of health of Nottinghamshire, which contains an account of the water-supplies of the county and of the manner in which the sources of such supplies may be encroached upon by authorities beyond the county limits. The account in question was, we imagine, prompted by the proposal of the corporation of Lincoln to take water from the north of Nottinghamshire for the supply of the city of Lincoln, where the well-known epidemic of enteric fever revealed the dangers of the existing river supply. Dr. HANDFORD, whose report is illustrated by a useful map, has for many years made a careful study of the water-supplies of the county, and he is satisfied that a shortage of water is certain to occur sooner or later. As is probably well known, the difficulty of obtaining an abundant supply for the city of Nottingham itself is one of the obstacles in the way of substituting a water carriage system of excrement disposal for the conservancy system which now prevails and which has been held responsible by the medical officer of health for the undue incidence of enteric fever in that city.

Nottinghamshire is supplied with water mainly from the pebble beds of the bunter sandstone which has a narrow outcrop along the west of the county north of Nottingham. To the east this bunter sandstone is overlaid by the keuper marl which in places attains a thickness of several hundred feet. Although there is in this bunter sandstone a large reservoir of underground water, it is only near the outcrop that it is palatable and has a moderate hardness. Where it has been over-pumped and the level lowered the hardness is enormously increased, and where the water is reached by piercing the keuper beds its character is altered and its hardness is so great that it is not usable—a fact which the city of Lincoln discovered to its cost after boring for 2200 feet; and this city has now obtained powers to sink a well in the bunter sandstone at Elkesley near the outcrop from which to take 3,000,000 gallons of water daily over the Lincolnshire border. The usual arrangements have been made by virtue of which the people of Nottinghamshire through whose districts the Lincoln mains run "get the first drink," but nevertheless Dr. HANDFORD thinks that conditions may subsequently arise by which, while the bunter sandstone may be supplying water to Nottinghamshire, Lincoln, and parts of Derbyshire, Nottinghamshire will be obliged to seek its future supplies from the Derwent and from the Lincolnshire limestones. He questions, indeed, whether the bunter sandstone of the county will suffice even until 1941 to supply the needs of the city and county of Nottingham as well as to supply Lincoln with 3,000,000 gallons daily. We shall not follow Dr. HANDFORD into his careful and detailed consideration of the subject, as our object here is national rather than local. We wish to emphasise the need for dealing with the problem of the water-supply as well as other matters obviously incidental to it in a scientific as well as comprehensive fashion by the formation of large local bodies having jurisdiction over groups of catchment areas and exercising control in all matters relating to water-supplies and sewage disposal as well as, in estuaries, over shell-fish intended for human consumption. It is clear that so long as a river is in the hands of the numerous local authorities along its banks no real progress will be made in the purification of its waters. B will not purify its sewage so long as A pollutes the river from above and C contaminates it below, and similarly A will not concern itself were referred to the principal epidemic diseases, against 567 and 470 in the two preceding weeks; of these 434 deaths, 152 resulted from diarrhœa, 104 from measles, 60 from diphtheria, 45 from "fever" (principally enteric), 39 from scarlet fever, and 34 from whooping-cough, but not one from small-pox. The deaths referred to these epidemic diseases during the week were equal to an annual rate of 1·4 per 1000, against rates declining in the four preceding weeks from 2·0 to 1·5; in London the death-rate from these diseases last week did not exceed 1·3 per 1000. No death from any of these epidemic diseases was registered last week in Rhondda, Leyton, Wolverhampton, Northampton, Hornsey, or in ten other smaller towns; the annual death-rate therefrom, however, ranged upwards in the other towns to 4·1 in Wigan, 4·4 in Huddersfield, 4·9 in Rotherham, and 8·6 in Middlesbrough. The 152 deaths attributed to diarrhœa in the 76 towns showed a further decline of 37 from the numbers in recent weeks, and were fewer than in any week since the end of July; the highest annual death-rates from this cause during the week were 1·8 in Preston, 2·0 in Great Yarmouth, 2·3 in Smethwick, and 2·5 in Middlesbrough. The fatal cases of measles, which had increased in the seven preceding weeks from 31 to 99, further rose to 104 in the week under notice; they caused death-rates equal to 2·5 in Rotherham, 2·9 in Tottenham, 3·9 in Huddersfield, and 6·0 in Middlesbrough. The 60 deaths from diphtheria showed a further decline of 13 from the high numbers in recent weeks, the highest death-rates from this disease being 1·0 in Hull and 1·3 in Reading. The 45 deaths referred to "fever" showed a further increase, and exceeded the number returned in any previous week of this year; the death-rate from "fever" was equal to 1·1 in Bolton and 1·2 in Wigan. The 39 deaths from scarlet fever also exceeded the numbers in recent weeks, and caused annual rates of 1·1 in Salford and in St. Helens, and 3·0 in West Bromwich. The 34 fatal cases of whooping-cough showed but a slight increase upon the low number returned in the previous week, but showed an excess in Willesden and in Wigan. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased in the nine preceding weeks from 2855 to 3852, had further increased to 3861 on Saturday, Nov. 14th; the number of new cases of this disease admitted to these hospitals during the week under notice was 500, against 507 and 512 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily increased in the four preceding weeks from 159 to 276, further rose to 310 in the week under notice, but were 23 below the corrected average number in the corresponding week of the five years 1903–07. The causes of 47, or 0·9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were again duly certified in Leeds, Bradford, Hull, Newcastle-on-Tyne, Nottingham, Leicester, and in 51 other smaller towns; the 47 uncertified causes of death in the 76 towns included, however, nine in Liverpool, six in Sheffield, five in Birmingham, and four in Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 16·2 and 15·4 in the two preceding weeks, rose to 16·9 in the week ending Nov. 14th. During the first seven weeks of the current quarter the annual death-rate in these eight towns averaged 14·5 per 1000, and exceeded by 0·3 the mean rate during the same period in the 76 English towns. Among the eight Scotch towns the death-rate during the week under notice ranged from 11·1 and 11·9 in Aberdeen and Perth, to 18·5 in Leith and 19·1 in Glasgow. The 597 deaths in the eight towns showed an increase of 54 upon the number returned in the previous week, and included 68 which were referred to the principal epidemic diseases, against 71 and 55 in the two preceding weeks; of these 68 deaths, 24 resulted from diarrhœa, 17 from whooping-cough, 12 from diphtheria, and eight from scarlet fever, but not one either from measles or small-pox. These 68 deaths were equal to an annual rate of 1·9 per 1000, which exceeded by 0·5 the mean rate from the same diseases in the 76 English towns. The deaths attributed to diarrhœa in the eight Scotch towns, which had been 34 and 29 in the two previous weeks, further declined to 24 in the week under notice, and included 12 in Glasgow, five in Edinburgh, and two each in Dundee, Leith, and Greenock. The 17 fatal cases of whooping-cough showed an increase of 11 upon the low number in the previous week; 13 occurred in Glasgow and three in Aberdeen. The 12 deaths from diphtheria exceeded the number in any recent week, and included four in Glasgow, three in Dundee, and two in Aberdeen. The eight fatal cases of scarlet fever also exceeded recent weekly numbers; four were recorded in Glasgow and two in Edinburgh. The deaths referred to "fever," which had been five and six in the two preceding weeks, further rose to seven last week, of which six were certified as enteric and one as cerebro-spinal meningitis; all these seven deaths referred to "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 56, 86, and 116 in the three preceding weeks, further rose to 126 in the week under notice, and exceeded by 22 the number returned in these towns in the corresponding week of last year. The causes of 27, or 4·5 per cent., of the deaths registered during the week in the eight towns were not certified; in the 76 English towns during the same week the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 16·0, 20·4, and 23·8 per 1000 in the three preceding weeks, declined again to 19·3 in the week ending Nov. 14th. During the first seven weeks of the current quarter the death-rate in the city averaged 18·8 per 1000, whereas the mean rate during the same period did not exceed 14·2 in London and 13·2 in Edinburgh. The 146 deaths of Dublin residents during the week under notice showed a decline of 34 from the high number in the previous week, and included eight which were referred to the principal epidemic diseases, against 11, 9, and 15 in the three preceding weeks. These eight deaths were equal to an annual rate of 1·1 per 1000; the rate from these diseases in the same week was equal to 1·3 in London and in Edinburgh. Of the eight deaths from these epidemic diseases in Dublin last week, four resulted from diarrhœa, two from "fever," and one each from measles and whooping-cough, but not one from scarlet fever, diphtheria, or small-pox. The fatal cases of diarrhœa and of "fever" showed a decline from the numbers in the previous week. The 146 deaths from all causes during the week included 30 of infants under one year of age and 31 of persons aged upwards of 60 years; both these numbers showed a considerable decline from those in the previous week. Three inquest cases and four deaths from violence were registered, and 61, or 41·8 per cent., of the deaths occurred in public institutions. The causes of seven, or 4·8 per cent., of the deaths in Dublin last week were uncertified; the proportion of uncertified causes of death in London last week did not exceed 0·1 per cent., while in Edinburgh it was equal to 4·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: A. H. H. Vizard to the *Leander*, for duty with torpedo-boat destroyers; A. I. Sheldon, to R.N. Hospital, Portland; and C. T. Baxter, to the *President*, additional, for three months' course at Middlesex Hospital. Surgeons: W. R. Harrison, to the *Imogene*, additional, and on recommissioning, undated; T. A. Smyth to the *Vernon*; P. M. Rivaz to the *Speedy*; D. D. Turner to the *Espiègle*, additional, for Dartmouth College; and Herbert Stone to the *Cochrane*. The following have been entered in the Royal Navy as Surgeons, with seniority of Nov. 6th: W. A. H. McKerrow, F. G. Hitch, T. R. L. Jones, C. F. Bainbridge, J. Glaister, A. V. J. Richardson, F. H. R. Black, W. Mearns, A. C. Wilson, E. J. H. Garstin, F. W. Quirk, S. L. McBean, G. R. McCowen, and W. Bradbury, all to the *Victory*, additional, for course of instruction at Haslar Hospital, and J. H. Burdett.

INDIAN MEDICAL SERVICE.

Lieutenants to be Captains (dated Sept. 1st, 1908):—Cadwallader Edward Palmer, Carl Henry Reinhold, Broderick rarer in its appearance than it has been amongst men, and we are entitled to consider that had it been present it would have come out as it has in many members of the male sex who have been severely handicapped by disadvantages of nurture and education. But certain women in former ages have enjoyed equal chances with men. An example comes readily to mind from the History of Medicine which tells of the mediæval lady graduates of the Salernitan school; but it is noteworthy that their successes did not make sufficient mark to enable women to retain the position won for them in medicine by Trotula and her compeers. It may be conceded fairly that medical women of the present day are entering the lists on equal terms with medical men, at least as regards education; it will be interesting to see what proportion of medical women as compared to men 50 years hence have contributed unmistakeably to the advancement of their science. And whilst speaking on this subject we desire to enter a protest against the common remark that women's equality with man will give the final blow to the "spirit of chivalry." Surely it should foster a new chivalry, greater than the old, extended by men not to *helpmeets* and *sympathisers* but to competitors who will still be entitled to it because they are women. In the calling of medicine the conditions appear to us to be singularly favourable to the exhibition of so knightly a temper in the professional relations of medical men to medical women.

But the point which it concerns us more to examine is the physical disability of women for executive government, an objection to which a contemptuously curt dismissal is given in "The Human Woman," which considers under this head the question of maternity only. It takes no account of the fact that every normal woman during the most useful years of her life is subject to a recurrent physiological process which is always liable to become pathological. This being the case, it cannot be said that women enjoy *equal health* with men. The assertion that women in primitive races or in peasant classes do what we consider men's work is beside the mark, for we have to consider the normal health of women of the cultured classes of a civilised nation on whom, if on any, the responsibilities of government would naturally fall. We are *repeatedly* assured in "The Human Woman" that 82 per cent. of the women of this country earn their own living. We should be interested to know what percentage of women suffer periodically from a physical incapability which may be prostrating and is for a few days in every month so severe as to interfere seriously with the sufferer's power of attention to work. We do not deny that many women work and suffer, but we cannot agree that such martyrdom, heroic though it be, can ever be compatible with such efficiency as is essential to the supreme guidance of State affairs. This argument may appear to cast a shadow upon the medical skill of the day, but it must be remembered that no physician can shield his patients from the tax which their bodies pay upon their heritage of civilisation. And even though it were possible that a perfect preventive medicine should in the future relieve women of the diseases incidental to their sex, the supreme blessing of motherhood will never be withheld from them whilst the race endures. It may appear a *reductio ad absurdum* to suggest the situation of a Cabinet Minister obtaining leave of absence at the call of maternity, but such a possibility must be considered resolutely before women are allowed admittance to Parliament. Lady Grove would minimise the inherent sex differences of human nature. Sex forms an infinitely wider psychical division in the human race than does any distinction of class when external things have been stripped away, and the reason is that the psychical kinship which binds together the members of each sex is the inevitable complement of their physical kinship. It follows that the antithesis of the two sexes must ever be the most ineradicable fact of human nature, though Lady Grove seeks to controvert the fact. Nietzsche hardly overstated the case when he thundered forth, "It has not yet entered into the heart of man to conceive how foreign to each other are the nature of man and of woman." But there may be firm alliance between foreigners, and with certain of the motives at the root of the struggle for "women's emancipation" many men must be in agreement. The story is as old as the human race, for in the woman's present protest there rings the echo of an exceeding bitter cry from out the ages, the cry of a weaker sex in a tyrannous and degrading subjection to a stronger, and in so far as women's emancipation means the wiping out of the last traces of concubinage from the state of marriage we are in full sympathy with it; but may this not be accomplished by the home influence of enlightened womanhood acting through their menfolk? We have no space to discuss the evolution of the present relations of the sexes into the origins of which Lady Grove enters in a boldly speculative manner, taking the view that the woman was in the beginning "the race" and man the mere fertiliser, but begging the question of how he came to be the "super-woman" in a piece of reasoning which we must qualify as superficial. It is something more than doubtful whether a substantial diminution of sexual self-consciousness will ever come about to lift the human race to the heights of which Lady Grove dreams, for the desire of the woman will ever be to the man, and of the man to the woman. We will leave the case to our readers with a quotation from this clever book which we have read with more admiration than conviction. The passage refers to the physical strength of certain rare women, and a Hungarian lady is mentioned who served in the Revolutionary army of 1848 and who, "under the name of Karl, attained the rank of first lieutenant of Hussars. At this point, however, an artillery major stopped her military career by marrying her," which we make bold to consider is the very best thing that could have happened to her: she showed herself a "human woman." And that, as the lawyers say, is our case.

The Surgery of Spinal Caries.

The presidential address delivered by Dr. T. S. Kirk at the Ulster Medical Society on Nov. 5th possessed much interest, for it dealt with the operative treatment of tuberculous caries of the spine, and it must be acknowledged that hitherto this morbid condition has not yielded much satisfaction to those surgeons who have ventured to

Frequently a patient dies here in whose case we have for months used the utmost efforts to cure or relieve, and make an accurate diagnosis, and then no opportunity is given of proving the correctness of the diagnosis. I am quite satisfied that if patients or their friends were informed that people would not be admitted into the hospital, except in cases of accident or sudden illness, unless permission was previously given to inspect the body in the event of death, they would consent to it, and it would be done as a matter of course. Under the present circumstances, in a large number of instances, when permission is at first refused, it is given as soon as we offer money. But this is a bad habit, and I seldom yield to it. Again, in a large number of cases, the persons who refuse permission are not the immediate relatives, but mere acquaintances; and though the former would consent, the latter urge them to oppose the measure, for the mere purpose of looking friendly, or exerting influence and being busy. It frequently also happens that patients are never visited while in the hospital by either relatives or acquaintances, so long as they are alive, but as soon as they die, ten or twenty persons come forward to prevent the body from being opened. I am quite sure that if it were made a rule to admit none (except indeed urgent cases) but with the understanding that they should be opened if they died, it would be cheerfully assented to. I am satisfied that the public feeling would change on the subject,—that the world might be brought to consider that we had not paid proper respect to the deceased unless we had ascertained by examination after death, the precise nature and cause of the complaint, and communicated the true state of the inside to the friends. This is always done in the case of the highest personage of the kingdom; and every soldier is opened, and whatever may be the part of the world in which he may have died, an account of the inspection is transmitted to the army medical board at Woolwich. Unfortunately, many do not distinguish between dissection and inspection—do not know that while dissection means cutting up piece by piece, inspection is merely making a cut, looking in, and sewing the cut up again. Whenever I die I hope to be carefully inspected.

"Audi alteram partem."

THE LATE SIR HENRY A. PITMAN: A CENTURY'S RETROSPECT.

To the Editor of THE LANCET.

SIR,—The student of historical medicine cannot but note the passing away of Sir Henry Pitman. The historic imagination covets landmarks, and a life which covered a century and was passed in association with many of the leaders of British medicine may afford us such tokens. By these we may be helped to discern the march of our art, its periods and its masters, during the last few generations.

Sir Henry Pitman was born in 1808, the year before the birth of Darwin and of Oliver Wendell Holmes. (Many other men of note were born in 1809—Gladstone and Lincoln, Tennyson and Fitzgerald and Poe, Mendelssohn and Chopin; it was a "year of momentous births," like 1769, when Napoleon, Wellington, and other famous men came into the world.) When Sir Henry Pitman was born our country was in the throes of the Great War. He was already seven years old when that war was closed by the battle of Waterloo, and the leaders of medicine and other sciences in our own land and France could once more come together. English savants were again welcomed by Cuvier and Berthollet, by Dupuytren and Laennec.

The period from the death of John Hunter in 1793 until 1820 may be called the Epoch of the Pupils of the Hunters—Baillie and Abernethy and Astley Cooper and the rest—as it was, perhaps, in the northern capital the epoch of the pupils of Cullen and of the Monroes. Young Pitman knew the generation that followed these—the era when in London Lawrence and Brodie, Bright and the younger Babington were in their prime. He had heard Guthrie lecture; he would tell how W. F. Chambers kept the notes of his cases in Latin, of the mordant eloquence of J. A. Wilson, of the elder Southey, and Billing, and Aston Key, and Clift, and many more. But Sir Henry Pitman's life was bound up with that of the Royal College of Physicians. Of his long years of service to the College he loved to speak and to tell how he had read through its centuries of Latin annals, how he spent long years upon their index, and how the Grant of Arms was once lost until the precious parchment was discovered by one of the Fellows in a casual shop. Sir Henry Pitman knew 13 successive Presidents of the College, from Halford who came to the chair in 1820 down to the distinguished holder of the office to-day. He was indeed examined by Sir Henry Halford in Latin for the College Licence. Thus through the life now closed we seem to be brought into touch with the courtly figure of that most aristocratic of physicians, the trusted adviser of four successive sovereigns, and the undisputed head of his profession in London for 20 years from the death of Matthew Baillie in 1823. Sir Henry Pitman knew Halford's successor, Dr. Paris, an accomplished chemist rather than a man of extensive practice, whose chief fame rests on his literary work in pharmacology. It was under Dr. Mayo that Sir Henry Pitman began his work as registrar of the College; he found his President keen and intelligent, despite a certain hesitation in his manner.

But the ideal President of all his experience was Sir Thomas Watson. He was, Sir Henry Pitman would say, a most amiable man, with a felicitous manner, the outcome of his own happy nature. "I never heard him speak an evil word of any one. Any letter he wrote was short and beautifully expressed. Sir Roundell Palmer, responding at a Harveian dinner, said that if he wanted happy expressions and good language he would go to the Royal College of Physicians." In Sir Henry Pitman's earlier days the President was still chosen, under statute of Henry VIII., by the eight College "elects" from among their own number; it was not until 1860 that the choice was given to the whole body of Fellows. At the date of his birth the College was housed in Warwick-lane; its removal to Pall Mall East was celebrated with much ceremony in 1825. The changes of the century may be illustrated from the College Pharmacopœias. That issued in the year after Pitman's birth introduced chemical nomenclature and admitted arsenic and digitalis for the first time; quinine, morphia, strychnia, and ergot had to wait until 1836.

No attempt can, however, be here made to measure the advances witnessed by our venerable friend during his long life. The stethoscope, the microscope, the thermometer, the testing of urine and of blood,—all these were brought into use in medicine within that century of life and they have opened up undreamt-of vistas in the science of our art. It may be that therapeusis has not kept pace with diagnosis, yet the age has been so full of expanding medical knowledge that to pass from 1808 to 1908 seems like going from darkness into light. What may be looked for in the century to come?

I am, Sir, yours faithfully,
R. HINGSTON FOX.

London, W., Nov. 16th, 1908.

THE ETYMOLOGY OF ASPHYXIA.

To the Editor of THE LANCET.

SIR,—The difficulty in explaining how the word asphyxia has acquired its present meaning, "suffocation" or deprivation of air or oxygen, must have occurred to many of your readers. Asphyxia (ἀ priv. and Σφύξις the pulse) means pulselessness or stoppage of the pulse. Σφύξις is derived from σφύζω "to throb." But pulselessness is not a feature in what we call asphyxia, and under the heading Asphyxia in Sir James Murray's "New English Dictionary" the following comment on this discrepancy appears: "It indicates a curious infelicity of etymology that the pulse in asphyxiated animals continues to beat long after all signs of respiratory movements have ceased."

The pos-ible solution of the difficulty is that the ancients, noticing that the arteries after death contained air and not blood, believed that during life they were air-ducts ramifying from the trachea called the "arteria aspera." Therefore, the word artery is probably derived from 'Αήρ (air) and τηρέω (I guard); and as the pulse-beat itself was attributed to the rebound of air or "vital spirit" in the arteries or air carriers it follows that the word asphyxia acquired the double meaning, stoppage of the pulse and deprivation of air. In the latter sense the term has survived. Thus an ancient error

Most surgeons will not be in accord with Dr. KIRK as to the bad results of the ordinary methods of treatment in early cases; in fact, in the average early case of spinal caries immobilisation gives excellent results, bony union taking place without the formation of an abscess. It is very definitely an innovation to adopt operative procedures in early cases and we shall watch with interest the further development of the method.

Annotations.

"Ne quid nimis."

VEGETARIANISM AND PHYSIQUE.

PHYSIOLOGICAL considerations have long disposed of the view that a purely vegetarian diet ministers best to the needs of the human body, and although objection has been raised against physiological reasoning on the ground that it was largely theoretical a good deal of practical evidence has been forthcoming which has justified all speculation. It is well established, for example, that the individual who subsists upon an exclusively vegetable diet is far more susceptible to the attacks of disease than is the consumer of animal food. In short, the former's power of resistance to disease is decidedly weakened, for the reason that, after all, he is underfed, or in chemico-physiological terms, he fails to realise a sufficient intake of protein substance which makes for bodily energy, not to mention intellectual capacity. Every day as knowledge advances and powers to add to that knowledge are increased is the view strengthened that vegetarianism is a fallacy. The vegetarian school has pointed with triumph in its own mind to the oriental peoples as examples of physical strength and endurance supported alone by a vegetarian diet. These examples in the light of an exceedingly interesting practical inquiry on the subject can no longer serve the arguments of the vegetarian advocate. We refer to a study of the problems of nutrition connected particularly with the well-being and physique of the teeming natives of Bengal in relation to their diet which consists principally of rice. The investigation was undertaken by Captain D. McCay, I.M.S., the professor of physiology at the Medical College, Calcutta, and it will be admitted, we think, that he has added a masterpiece of physiological inquiry to previous contributions. Theoretical considerations may be left out, although they are obviously of interest compared with the results of practical observations. Experimental details, also, though full of scientific interest, may be omitted, but it is enough to say that the results fully justify the conclusions arrived at. Anyone, we are told, who has seen the ordinary Bengali coolie at work will not require much statistical evidence to convince him of the marked superiority of the European; men have often to be employed in India for work that women will do in England. Again, from an insurance point of view the life of the Bengali is very inferior to that of the European. In spite of the fact that the Bengali exists on a protein metabolism very close in amount to that stated by Chittenden to be sufficient, his powers of resistance to disease are impoverished owing to an unreplenished condition of the blood accompanying a low protein intake. Nor is the function of the kidneys the better for a low protein intake, for kidney disease is more common among natives than among Europeans, whilst amongst the upper middle classes the extreme presence of glycosuria would prove conclusively "that the danger of an excess of carbohydrate intake is even a more real and present one than that of proteid excess." From this it would appear that the human machine in health is able to eliminate more completely the toxic products elaborated from a generous diet of protein than from a diet overstocked with carbohydrate. At all events, in the latter case the resisting power of the tissues to disease is decidedly lowered, so that diabetes, pneumonia, tuberculosis, spreading gangrene, and so forth are very prevalent amongst the Bengalis who subsist on a beggarly protein diet. It follows that vegetable food, unless consumed in large quantities, does not yield a sufficiency of protein, and therefore, in order to obtain this sufficiency, a quantity of carbohydrates has to be consumed simultaneously which places a strain upon the resources of the body ultimately leading to a reduced vitality which is favourable to microbial invasion and its results.

THE METROPOLITAN WATER-SUPPLY.

THE report of the Water Examiner on the condition of the metropolitan water-supply during the month of August has been issued and does not call for any exceptional comment. The condition of the London water during the month appears to have been as satisfactory as can be expected under existing conditions, thanks to the absence of floods on the Thames, although the mean rainfall for August was all but an inch above the mean average for that month. It is probable, however, that this increase of rainfall will be reflected in the bacteriological report for September. As it was, 13·6 per cent. of 100 cubic centimetre samples of filtered Thames water contained bacillus coli in August. This report also contains tables giving a summary of the state of the various water-supplies during the three summer months—June, July, and August. Comparing this quarter with the same months of 1907 it is found that during this year the raw waters contained the more bacteria, and in the case of raw Thames and Lea waters a larger proportion of samples contained typical bacillus coli in one cubic centimetre of water. There were, however, slightly fewer microbes of intestinal origin in the filtered water, which is perhaps to be accounted for by additional storage before use. The report further states that "chemically, the *raw* Thames water was less turbid and discoloured, and also contained less albuminoid nitrogen and absorbed less oxygen from permanganate in the 1908 summer quarter than in the 1907 quarter. The *raw* Lea and New River waters were slightly worse in 1908, as judged by the foregoing tests, except as regards albuminoid nitrogen in the case of the Lea. As regards the *filtered* waters the 1908 results compare favourably with the corresponding 1907 results with the exception of the New River and East London (Lea) districts." The further improvement of the London water-supply depends now upon increased storage accommodation, and it will be within our readers' knowledge that extensive works are at present being undertaken by the Metropolitan Water Board to construct a new pumping-station and reservoir at Island Barn, West Molesey. It was high time that the Board took advantage of the powers which were obtained by the Lambeth Waterworks Company in 1900 but which hitherto have been resolutely opposed by the local authorities on financial grounds, and this in spite of the fact that the Lambeth water has often been notably unsatisfactory. The water is to be taken from the Thames through an open conduit taking eight feet of water when the river is at normal level. The pumping engines will be able to raise 25,000,000 gallons daily. Mr. C. E. Hearson, chairman of the works and stores committee of the Board, in an address which he delivered recently when Mr. John Burns "turned the first sod," said that the occasion marked the commencement of a series of reservoirs which would add a storage capacity of 4700 million gallons to the of, the enormous amount of work done by others on immunity and of the work which probably lies at the root of these experiments—I mean that done on cytolytic processes. Mr. Walker in his reply confessed, in fact, to ignorance in regard to this.

I hardly think it necessary to pick to pieces his criticism of my remarks, for he has so placed these, which were only published in brief abstract, out of the context, that I should have to write out what I said in full to make the position intelligible. To give an instance, surely "work on immunisation" is different from "immunisation," as quoted by Mr. Walker as a positive fact! I must therefore be general. In the first place, I never said that the results of the work of others coincided in every particular with the results of Mr. Walker's experiments—that would be too much to expect of any work—and I pointed out differences. In the second place I have a good imagination but I cannot recognise the ultimate difference between experiments on immunity and experiments on curative processes based on induced immunity. For Mr. Walker to say that experiments which "deal with the immunisation of mice beforehand to tumours which were subsequently introduced ...... have no bearing upon the treatment of already existing and well-established tumours" is—even if it were true, which it is not—to emphasise his ignorance of the nature of the process and the work done. Direct contradiction is given, if any were needed, by the experiments of Clowes and others on this very subject.

Then in regard to priority. In the historical portion of a paper by Bashford, Murray, and Cramer[2] they state that Jensen (in 1901) "observed the complete disappearance of tumours from mice that had been successfully inoculated. He added, however, that the 'results of attempts to cure mice of tumours have hitherto been uncertain.'"

Again: "Borrel ...... recorded suggestive experiments directed to obtaining a polyvalent immune serum against human cancer." Also: "Clowes ..... the animals in which spontaneous absorption had occurred were stated to possess a specific antibody in their serum which on injection into animals with transplanted tumours *exerted a curative effect*" (italics mine). And so on. There are several very important and interesting papers in the Third Scientific Report of the Imperial Cancer Research Fund dealing with the immunity established in rats to mouse tumours and the immunising effects of other tissues, including the work done with testis. Regarding Mr. Walker's claim to "cure" mouse cancer with "testis serum" I have already spoken—and the less said about it the better!

In conclusion, I only wish there were a hopeful outlook for the experiments, but I think if Mr. Walker will make himself familiar with work on cytolysins generally (of which he confessed ignorance) he will, when he fully understands all they imply, be as doubtful as other workers have been who have considered the question of making a cytolytic *serum* for human cancer on these lines. All my criticism would have been avoided if Mr. Walker had acknowledged the work of others—whether he conscientiously considered that he was first in the field or not. I make no attack on Mr. Walker and unwillingly allow myself to say this much in answer to his attempt to clear himself. I shall not, therefore, discuss the matter further.—I am, Sir, yours faithfully,

Liverpool, Nov. 14th, 1908. W. BLAIR BELL.

THE NEUROTONE.

To the Editor of THE LANCET.

SIR,—May I state in your able journal that I am not the inventor of "The Neurotone or Neurostone," as it is termed; but during many years of research work in electricity I have found it a perfect appliance to accomplish the object I had in view.

I am, Sir, yours faithfully,
J. A. GRANT.

Ottawa, Nov. 4th, 1908.

COW'S MILK: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—I should feel very much obliged if some of your readers who have patients unable to take ordinary cow's milk would be so good as to try those patients with milk from cows which are not in calf. The milk that is supplied daily in this country is in 99 per cent. of cases obtained from cows in calf. My experience so far has been that patients, especially children, who were unable to digest the ordinary market commodity were when given milk obtained from cows not in calf able to take the latter and thrive on it. The difference between the two milks is considerable, as the drain of the embryonic calf must seriously interfere with the quality of the pregnant cow's milk.

I am, Sir, yours faithfully,
G. ARBOUR STEPHENS.

Swansea, Nov. 9th, 1908.

BELFAST HEALTH COMMISSION.

(FROM A CORRESPONDENT.)

(*Concluded from p. 1483.*)

WITH reference to the deplorable state of affairs in Belfast pointed out by the recent Health Commission, that the corporation is without information as to the details of deaths occurring in its district beyond the mere numerical particulars obtained from the Registrar-General's official publication—information without which no sanitary authority can adequately search for, or cope with, causes of disease and death—it is clear the excuse of the committee of the corporation, that it is the duty of the Local Government Board to promote the legislation suggested by the Health Commission in this direction, is mere fencing with the question. The corporation of Belfast should itself promote a Bill and "the most effective and natural way of dealing with it (the question of vital statistics) is to follow the precedent of the English and Scottish Registration Acts, even if such a method involves fresh legislation; and we recommend that this should be done," says the Health Commission, and it further adds: "In view of the importance of the information as to the details of deaths occurring within the city, we regret that the corporation did not fall in with the suggestion made to them in October, 1907, by the Local Government Board for Ireland, which, pending legislation, would have enabled them to get the information desired." There can never be any proper public health administration in a city until the medical officer of health has trustworthy vital statistics, and, as the Health Commission reports, any health reforms attempted without such information must be in the nature of leaps in the dark. Imagine a city where, as the Health Commission says, the corporation does not know the causes of death among the children, where "the corporation are completely in the dark as to the places where deaths in the city are occurring, even from such important diseases as phthisis, tuberculosis, pneumonia, cancer, diarrhœa, or from diseases which may be due to industrial causes, to poverty, or to any of the other conditions which may be thought of as associated with modern town influences." Dr. H. Whitaker, the former medical superintendent officer of health, often drew attention to the defects in his sources of information; nay, more, Mr. H. W. Bailie, in his report just issued for 1907, says in reference to this matter, "We are where we were a year ago."

In the face of these facts, why does the corporation not promote a Bill itself and get this matter made right, which is the very foundation of public health, and put into its Health Bill all other matters—the control of the milk-supply, certain powers for sanitary administration (as advised by the Health Commission), the getting rid of the abomination of double tenement houses, the reorganisation of the antiquated system by which there is a medical superintendent officer of health and 14 district medical officers of health, so as to make the medical superintendent officer of health the real head of his department, with personal control of everything pertaining to the public health, &c., so as to place Belfast on the level, in public health administration, with any city in England or Scotland? When anyone suggests to the corporation of Belfast the trial of public health measures which have proved efficacious in other cities they always get the same answer, "We have no powers," and the bogey of the Local Government Board is trotted out. In reply, it may be said if you have not powers your duty is to get them. Sheffield and Bolton got special Acts passed to enable them to make pulmonary tuberculosis compulsorily notifiable, Manchester and Bristol went for special legislation on the milk question, and Huddersfield was complimented by a Committee of the House of Commons for leading for protection. In summer there are few days when the temperature is so high as to be uncomfortable. The head and eyes are protected from the glare of the sun and from the great heat by keeping the head either in the shade of some building while the rest of the body is exposed or by the use of a sunshade. If at any time the high temperature causes discomfort the patient is carried into the shade. At the beginning of the treatment the time during which the patient is exposed is graduated so as to prevent undue sunburn. This may sometimes be avoided by keeping a sheet over the part. At times the patient should alternately lie upon his back and face so that all parts may be exposed to the sun. This treatment by recumbency and exposure to the sun is continued throughout the acute stage until there is evidence of complete cicatrisation. In nearly all cases this period amounts to several months and it may amount to years. When the patient is allowed to get up a brace is used which is both a crutch to carry the body's weight and an extending force to maintain traction upon the affected limb. This brace consists of a padded steel band which passes around the pelvis just above the great trochanter and a leg bar secured to this without a joint. This passes down the outer side of the leg to the sole of the foot and has a bolt which passes through a tube inserted in the heel of the boot. Two perineal straps are attached to the pelvic band. The perineal strap on the sound side is kept tighter than the other in order to afford counter-extension, while the bolt in the heel produces extension. Dr. M'Kenzie has treated 166 cases by this method with the following results. Eight patients died. Amputation was performed in two cases in which extensive suppuration had occurred. In 56 cases "first-class recovery" took place; a small proportion of the patients had good motion of the hip-joint and practically no shortening; others had ankylosis in good position. In only seven was there "poor recovery" (a femur moveable on the pelvis or long-discharging sinuses). The average time of confinement to the cot was six or seven months.

THE CHURCH AND SPIRITUAL HEALING.

BOTH on this and on the other side of the Atlantic there is a movement in the Church towards the consideration of matters connected with healing by other than physical means. On the other side of the Atlantic the Church has probably been led to initiate this movement on account of the extreme prevalence of the belief known as "Christian Science." In this country, however, a meeting which was held at Sion College on Nov. 16th owed its inception in main part to the discussion of the question at the recent Lambeth Conference. Various clergy and laymen attended the meeting, and it is stated that a motion was adopted to the following effect:—

> That in the opinion of this Conference the time has come to form a Central Church Council in the Diocese of London for the consideration of questions connected with healing by spiritual means, and that the Bishop of London be respectfully asked to nominate the members of the council.

We are glad that the Church is taking up this question, for the amount of evil done by unlicensed and quack professors of "faith-healing" is incalculable. When the Church exhorted its sons in sickness to call for the duly ordained ministers of the Church it was never meant that material means should be ignored. The true meaning of the sacrament of unction has been gradually lost sight of until, in one branch of the Church, it has become, in popular belief at all events, a mere viaticum for the dying and in no way a means of restoration to health. On this point we may perhaps refer to the Order for the Visitation for the Sick as published in the first Prayer-Book of Edward VI. in which there was a form for anointing the sick person should he so desire it; and in which prayer was offered that God would vouchsafe to restore to the patient his bodily health and strength and to send him release of all his pains, troubles, and diseases both in body and mind. So long as the skill of the physician is not neglected there is no reason why the offices of the Church and their effect upon the mind of the patient who believes therein should not be used. Every medical man knows perfectly well that a patient who desires to, and believes that he will, get well is far more likely to recover than one who, owing to carelessness or despair, meets death half-way.

LADY (RUSSELL) REYNOLDS.

WE much regret to announce the death of Lady Reynolds which occurred at her house, 3, Spanish-place, Manchester-square, on Tuesday last, Nov. 17th, after about a fortnight's illness. Her life was so full and energetic that the announcement will come as a shock to her many friends. Lady Reynolds was the daughter of Mr. William Plunkett, a member of the Fingall family, and was first married to Mr. C. J. Champion-Crespigny, but in 1881, being then a widow, she became the wife of Sir John Russell Reynolds and from that time forward was well known to many members of the medical profession for her keen interest in medical work in all its phases. Rather late in life and when his health was not particularly good Sir Russell Reynolds became President of the Royal College of Physicians of London, and in 1895, two years later, President of the British Medical Association, holding for a time the two important offices concurrently. It was only Lady Reynolds's great energy, tact, and resolute determination to protect her husband as far as possible from unnecessary encroachment upon his time, that enabled Sir J. Russell Reynolds to discharge efficiently the duties of these posts. The experience which she then gained of medical politics and the large acquaintance which she formed in the medical world made her a real authority upon such matters. Sir J. Russell Reynolds died in 1896 and from that time forward Lady Reynolds's life was largely absorbed by her strenuous attempts to do work for the good of the medical profession and for the public benefit through that profession. She became an indefatigable worker upon the lay committees of hospitals, especially of those hospitals with which her distinguished husband was connected, and in all questions which arose, where her counsel was required, she gave it in an outspoken manner, with an absolute sense of justice and from the point of view of one who appreciated the aims and objects of the medical profession. She was by birth, training, and instinct a Tory, and was opposed to the movement which is designed to obtain larger political responsibilities for women, but every act of her public life showed that if those responsibilities had devolved upon her she would have known how to acquit herself manfully. As it was she was a living proof of the amount of influence for good which a thoroughly brave and capable woman may become.

MEDICAL REFEREES AND LIFE ASSURANCE.

AT the opening meeting of the Life Assurance Medical Officers' Association on Nov. 4th, Dr. T. Glover Lyon, the president, occupying the chair, Sir Thomas Oliver read a paper on "Some Medical and Insurance Problems arising out of Recent Industrial Legislation." He pointed out that while the Workmen's Compensation Acts of 1897 and 1906 had imposed a serious burden upon employers, the effect had been rendered comparatively light through distribution of the risk by insurance, while the beneficial effect of the compensation on injured workmen should undoubtedly promote social betterment. As regards Germany, however, where such insurance has now been compulsory for 25 years

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT WASHINGTON.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

FESTIVITIES AT WASHINGTON.—PRIVATE RECEPTIONS AND THE SECRETARY OF STATE'S BANQUET.—A VISIT TO THE WHITE HOUSE.

New York, Oct. 13th.

IT was originally planned that during the week spent at Washington there were to be no festivities. The members of the Congress were to go to bed early and to attend exclusively to serious work. As might be anticipated this stern resolve broke down, at least to some extent. Not only were there a good number of private receptions but the Government itself gave a banquet in honour of the Congress. Mrs. Gardiner G. Hubbard provided motor-cars to take members to her country estate in the neighbourhood of Washington on the Wednesday afternoon. Unfortunately, this was the day of the joint meeting of the sections to hear the great discussion on Professor Robert Koch's opinions concerning the danger of bovine tuberculosis. As this discussion was prolonged till after 6 o'clock many people who had accepted were not able to avail themselves of Mrs. Hubbard's invitation. The same evening Dr. and Mrs. Charles W. Richardson were more fortunate in gathering in their house many members of the Congress. Already on the day of the opening of the Congress, on Monday, Sept. 28th, there had been a *conversazione* at the Corcoran Gallery of Art where the foreign delegates met their new American colleagues and renewed acquaintance with each other. Then the Cosmos Club very graciously made all the foreign delegates honorary members and several pleasant little dinners were given. But undoubtedly the greatest event of the week was the banquet given by the Secretary of State who in America is the next most important member of the Government after the President. In the new Willard Hotel, on the fourteenth or fifteenth floor, there is an enormous and lofty banqueting hall. What with the profusion of flowers and green garlands and shrubs, and even palm trees, it seemed at first as if we had arrived at one of the roof gardens that are becoming a feature in American life. But there were solid walls around us and even a gallery where the band was held in reserve to play various national anthems in honour of the foreign guests. After the guests had partaken of a substantial repast and various wines there followed the congratulatory speeches. Mr. Elihu Root, the Secretary of State, who to a large extent performs the duties of a Minister of Foreign Affairs, presided over the banquet and gave the foreign delegates an opportunity of admiring his eloquence. Naturally he made the first speech and he stated that it was on behalf of the Government of the United States, and still more on behalf of the people of the United States, that he wished to thank the members of the Congress for their devotion to the advancement of science. This cause had led many eminent authorities to travel a great distance so that they might contribute their share in reducing the burdens still borne by mankind. Mr. Root welcomed the men of science who had rendered the present age distinguished above all others for its science: "Citizens of lands, subject to many sovereigns, you come to us as soldiers of science and members of the same army, as you are all fighting the same foe and this on behalf of the same Republic of Learning. To whatever allegiance you may have subscribed you are all brothers in humanity." Mr. Root then proceeded to discuss the fact that progress seemed unattainable without incurring some loss. All refinements entailed the abandonment of those simple conditions in which health came and was maintained with but little effort. When we secured in our dwellings comfortable warmth we also created new conditions and these engendered new evils that necessitated the intervention of men of science to combat them. This struggle against disease is bringing about a union of mind and of hearts which will give birth to the brotherhood of man. Our united efforts will accomplish what was impossible whilst we were isolated. The individual man is no better to-day than he was 500 years ago, but he stands on the united, consolidated achievements of his predecessors and is therefore on a much higher level when he commences his individual effort. Thus man to-day can go far beyond the achievements of his ancestors. In the presence of the task now before the members of the Congress the ordinary work of government seemed unimportant. The congress was dealing with the very existence of man. On behalf of the Government, said Mr. Root, "we welcome you, we ask you to come again, we ask you to leave us your benediction as you go and to remember us kindly when you reach your homes." He thought appreciative Americans would feel the Congress was indicating a more humane and a more effective way of rendering mankind more efficient, while suffering less and living longer. Thus would the Congress contribute to raise humanity physically and morally.

Mr. Root, after the applause had subsided, called upon Professor Robert Koch who was greeted by the band with the "Wacht am Rhein" and with enthusiastic cheers from the audience. To the surprise of all, he delivered, in German, a humorous speech which is a sort of oratory that never fails to be well appreciated after a banquet. The Marseillaise and Professor Landouzy, Dean of the Paris Faculty of Medicine, followed. Professor Landouzy said that the French members were eager to see what in its youthful energy America had done, so they had crossed the Atlantic, the great ocean, "that brings us near more than it separates." After old Europe had learnt from America what could be done for agriculture, she had now seen the birth of young American science, a field where a rich harvest had also been gathered in. So active was the American radiography that it had brought into existence yet another milky way, and now to its 46 stars a brighter star was added which shone with the light of American science. Like the Magi from the East the delegates from old Europe came with the aurora of the rising day to salute the birth of American science.

As the band played "God Save the King" Professor G. Sims Woodhead rose and qualified the gathering as the apotheosis of the tubercle bacillus. This bacillus, about which they held divided opinions, was nevertheless destined to unite them all. They might argue about its character and origin but the more they differed the more they came together to discuss and they had the belief that these frequent international meetings all made for peace. Thus they would cherish tender memories of the tubercle bacillus long after it might have passed away, such as the memory of the warmth of the American welcome to that Congress. The British gave way to no one in their admiration for what had been done in the United States. Science was a great brotherhood but the Americans being more nearly related to the British they had a larger claim on the affections of the English people. All that had been done tended to bring closer together the two great nations which were united in the wish to preserve the peace of the world. In this policy no nation would join more heartily than the Mother Country on the other side of the water.

The representatives of Russia and Austria followed and then Dr. W. H. Welch (Baltimore) rose to explain that the Congress owed a great deal to Mr. Root, for he had befriended its promoters from the very first. At Paris it had been laid down that the invitation to meet in America could not be taken into consideration by the Second International Congress on Tuberculosis unless it was approved and endorsed by the American Government. There were only 24 hours to act, as the answer had to be sent while the Congress was still sitting in Paris. Fortunately, the Secretary of State granted an interview immediately. A mere statement of the case sufficed and a satisfactory cablegram was drawn up and sent to the American Ambassador at Paris. But for the active intervention of the Secretary of State it would not have been possible to carry the vote at the Paris Congress which decided where the third Congress should be held. Now that the Congress had met at Washington it had proved the means of enlisting the sympathy of the American Government and of the people. In America this was more important than in Europe, where it sometimes sufficed to obtain the help of a few persons in high authority. There never had been in the United States such a Congress and Dr. Welch added: "We have learnt more from you than you can possibly take away from us here." There was a flutter of excitement, especially among the French delegation, when the next speaker rose, for he was introduced as "Citizen Bonaparte, Attorney-General of the United States, and grandson of the King of of inspection of the water-supply. In the State of Minnesota it is now the rule not to analyse samples of water forwarded to the laboratory but to send out inspectors who, after an accurate survey, may then proceed to make field "plates" from the water on the spot. These plates are sent to the laboratory for incubation and examination. Thus Minnesota places inspection first and, if necessary, then begins a bacteriological examination on the spot. The system may seem expensive but, as Professor Connell observes, one epidemic of enteric fever prevented would save the expense of many years.

THE LOCAL USE OF EPSOM SALTS IN THE PRIMARY DRESSING OF BURNS AND SCALDS.

IN the October number of the *International Journal of Surgery* is published a paper by Dr. M. N. Stowe of Jesup, Georgia, on the local use of magnesium sulphate as a first dressing for burns and scalds. The paper was read at the thirteenth annual meeting of the Association of Surgeons of the Southern Railway at Birmingham, Alabama. He recommends the employment of magnesium sulphate because it gives instant relief and the inflammatory reaction is much reduced, while there is no risk of poisonous effects from absorption. Epsom salts are nearly always available and the dressing is very inexpensive, and it is also easily removed. In many cases no further dressing is required, but even when it is thought desirable to employ any other form of dressing later the magnesium sulphate is valuable as a primary dressing. Dr. Stowe uses the salts as follows: Where the burnt part can be immersed a saturated solution of the salts should be used and the part should be kept in it until no pain is felt on withdrawal. We may mention that water at 62° F. dissolves more than its own weight of magnesium sulphate. If it is not convenient to use a solution, the dry salts may be applied and covered with a wet cloth; or a thick paste may be made and placed on the affected part, such as the eyes or nose. The method is simple and it appears to be worthy of trial.

THE POSSIBILITY OF INTRODUCING SECRECY IN THE CERTIFICATION AND REGISTRATION OF DEATHS.

Dr. E. M. Smith, medical officer of health of the city of York, read a paper at the recent Congress held by the Royal Sanitary Institute at Cardiff on the subject of death certification and registration. Among other matters discussed in connexion with this important subject prominence was given both in the paper and in the speeches which followed to the desirability of obtaining a fuller and more accurate statement of the cause of death than the medical attendant now gives in some cases and to the possible conditions which would conduce to this end. It is hardly to be denied that the cause of death under the existing law is at times disguised to some extent owing to a desire not to hurt the feelings of surviving relatives, or in order not to gratify their curiosity as to the private history of the deceased. Survivors may also sometimes desire reticence as to material matters in order not to afford evidence to insurance companies likely to be injurious to the estate of the deceased. Deaths due to alcoholism and to syphilis were given as instances of those not now accurately registered for reasons such as those suggested, and the recommendations made in view of these circumstances were to the effect that medical practitioners should be paid by the State for death certification, that the certificates should be sent to registrars under cover, and that to relatives asking for copies of the certificate or to assurance companies a modified statement of the cause of death should be given and not a full copy. The question is one of public interest and is not easy of solution. It is of importance that the registration of deaths should provide absolutely trustworthy materials for the compilation of statistics and for the information of those concerned with the public health. There are, however, important uses for which the production of a full and accurate death certificate may be required, and if such a document facilitates the operations of life assurance companies it assists in a class of business of great public importance. The objects of such companies may be purely commercial so far as the relations of assurer and assured are concerned, but nevertheless the legislature would probably hesitate to enact anything which tended to hamper life assurance or to render it either more expensive or less secure. The medical man, from his point of view, rightly regards himself as the trustee of his patient's secret, although equally he appreciates the valueless nature of death statistics without accurate certification. The public, from their point of view, may also be justified in thinking that the dead are past being affected by the revelation of the cause of their decease, and that the interests of the living, on the whole, would be best served by a candid statement, open to inspection upon proof that such inspection would tend to further justice or to prevent injustice. The difficulty, no doubt, lies in the imposition of satisfactory conditions under which the full contents of the death certificate should be made known and in the fact that the candour of the medical man is likely to be proportionate in many cases to the stringency of those conditions. If, however, in certifying he earns a fee payable from the State he becomes even more conspicuously than now a State officer, bound as such to perform a public duty without fear or favour.

EXTRACTS OF MEAT AND SIMILAR PREPARATIONS.

A BULLETIN has just been issued[1] giving the results of a chemical study of various commercial products made from meat and of various adulterants of meat extracts. The investigation was initiated with a view of establishing standards for these preparations, many of which are widely advertised and highly recommended for invalids as concentrated nutritious foods. The brands examined included almost all the solid and fluid extracts of meat that are well known in the United Kingdom. It is interesting to note that American extracts of meat are now extensively prepared by the evaporation of the soup liquor obtained from meat which has been parboiled in the process of preparing canned meat. A first-grade extract of beef is prepared from beef alone, but inferior grades are obtained from the trimmings, including odds and ends of meat, muscle tissue and bone, or from the liquor in which corned beef has been cooked. In the latter case considerable quantities of nitrates and sodium chloride are present in the extract. The manufacturers claim that 100 pounds of soup liquor will yield one pound of meat extract. The products examined were divided into four classes—viz., solid and fluid extracts, meat juices, and miscellaneous preparations—and were judged by empirical standards. In the case of solid extracts the standard required not less than 75 per cent. of total solids, containing not more than 27 per cent. of ash, and not more than 12 per cent. of sodium chloride, or six-tenths per cent. of fat. It was also held that the nitrogenous compounds should contain not less than 40 per cent. of meat bases and not less than 10 per cent. of kreatin and kreatinin. Of the six solid extracts examined several fell below the definition in one or two points but they were satisfactory in most respects, the percentage of nitrogen much of the alcoholic precipitate of Koch's old tuberculin to produce the same effect. Tuberculin CL was well borne by patients and the results had been good in increasing resistance and delaying the process of tuberculosis, though it was no more a cure than was any other similar substance. Very small doses, 1-1000th milligramme, must be used at the commencement until ultimately 3-10ths of a milligramme might be administered. A reaction exceeding half a degree C. was avoided by maintaining the intervals of from 10 to 12 days between the injections. Professor Calmette also strove to obtain a constant increase of the opsonic index. When studied experimentally *in vitro* tuberculin CL showed an affinity for the lipoids constantly present in the serum of tuberculous men and cattle. These substances were probably lecithins. In this connexion Professor Calmette alluded to his researches upon the activation of cobra-venin by the free lecithin of serum. Hence tuberculin CL afforded an index of the affinity of the patient's serum for the products of the tubercle bacilli, and this gave a valuable means of controlling medication by tuberculin, hitherto a most difficult matter.

---

[1] Bulletin No. 114, Bureau of Chemistry, United States Department of Agriculture, by W. D. Bigelow and F. C. Cook, pp. 56 (1908).

The Bio-chemistry of the Tubercle Bacillus.

On the same day the biological chemists gathered in force and presented a series of papers upon the proteids of the tubercle bacillus, its immunising substances and enzymes, and upon the chemistry of the body during infection.

Dr. VAUGHAN (Ann Arbor) described his method of separating poisonous substances which would kill an animal in a few months in doses of from 75 to 100 milligrammes. The non-poisonous residue sensitised to the tubercle bacillus and was now being used in human cases of tuberculosis. It was yet too early to compare this method with older ones.

Dr. NOGUCHI (Japan) communicated through Dr. SIMON FLEXNER (New York) a lengthy study upon the action of soaps upon the vitality and immunising property of the bacillus tuberculosis. They were led to try this by the bactericidal activity and the complementary action of oleate soaps in conjunction with blood serum. They concluded that oleate soaps modified tubercle bacilli so that when subsequently inoculated into guinea-pigs they either failed to produce lesions or caused slighter ones than those shown by the control animals, with the result that death was postponed. These animals had acquired an immunity to virulent cultures, and either developed no lesions or far milder ones than did the control animals. The bactericidal effects of these soaps could not be reproduced by their component acids and bases. Dr. Noguchi believed that these lypoids were probably among the products of autolysis of lymph gland tissue which had been shown to be injurious to the bacillus tuberculosis by Conradi and Bartel.

Another paper from the Rockefeller Institute was that of Dr. EUGENE L. OPIE (New York), who had studied the enzymes of tuberculous tissue produced by inoculating the pleura. He found that the polynuclear leucocyte enzyme quickly diminished in activity after his inoculations. A second enzyme occurred in great abundance, only disappearing when caseation supervened. It digested proteid in weak acid media and it was probably derived from the epithelial cells of the exudate. These enzymes were inhibited by blood serum but not by that of the pleural exudate. Dr. Opie therefore believed caseation to be due to an autolysis by these enzymes when, through diminution of the vascular supply, they were no longer inhibited.

Dr. VON SCHRÖTTER (Vienna) reported an atttempt by Reitter and Stoerk to devise a means for the Diagnosis of Tuberculosis by a Serum Reaction. It consisted of a modification of the well-known method by carbolised sodium chloride. The precipitation of the colloids occurred in a higher percentage when an ethereal extract of tubercle bacilli was added to the solution in the proportion of ½ grain bacilli to 200 cubic centimetres of solution. In applying the method care must be taken to exclude such lipæmic conditions as diabetes, tumours undergoing regressive metabolism, and occasionally non-tuberculous infections. The method accordingly required confirmation by further trial.

A most valuable contribution to this subject was that of Dr. PAUL COURMONT (Lyons) upon the Agglutinating Power in Tuberculous Patients, with reference to Serum Diagnosis and Prognosis. He emphasised the indispensability of rigorous technique regarding choice of culture, its method of preparation, and the nature of the reaction in accordance with age and species, and he warned against its interpretation without coördination with the clinical symptoms. In suspicious cases positive reaction had great value. The information might be (1) general, where the information derived from it was equal to that of the conjunctival or cuti-reaction; but it did more, (2) for by testing the agglutinating power of serous effusions it assisted in locating the tuberculosis. The indication for prognosis was derived from the measure of agglutinative power, which was in inverse ratio to the virulence of infection. It was lacking in serious and advanced cases and increased during improvement.

Dr. ISHIGAMI (Osaka) followed with a paper in which he claimed to have succeeded in preparing two remedies of comparatively great efficacy and free from any detrimental reaction: (1) tuberculin-toxoidin, a chemical preparation from tubercle bacilli, suitable for incipient and apyrexic cases; and (2) an immunising serum for advanced cases. The former was used by injection in progressive doses. Under this treatment the body-weight and vital capacity increased, the bacilli broke down and agglutinated, the opsonins increased, and early cases were completely cured in from three to six months, and later cases also when the general nutrition was good; recurrences were rare. Statistics were given showing that the average number of injections required was 65. By the use of tuberculin-toxoidin in animals he had obtained an immunising serum which no longer caused the characteristic troublesome reactions in patients, and he claimed to have cured three cases of comatose cerebral meningitis with this serum.

Dr. CROFTAN (Chicago) presented an abstract of his studies on the Calcium Metabolism in a Case of Tuberculosis. He believed that the increased urinary excretion of calcium was due to its affinity for the deutero-albumose present in tuberculous foci, sputum, blood, and urine. This was a protective reaction, for experiments showed that the "pyrogenic" effects of this albumose ceased when it was combined with calcium. The therapeutic possibilities of this were indicated by a seeming immunity amongst workers in lime salts.

Dr. G. BERNHEIM and Dr. P. BARLIER (Paris) presented a joint report upon the Therapeutical Value of Tuberculins. This was opened by a comprehensive historical survey of the search for a specific remedy for consumption the world over, and was followed by a consideration of the therapeutic value of the various active and passive methods of producing immunisation which had been proposed. As regards passive methods, Dr. Bernheim and Dr. Barlier, relying upon the recent works of Bordet on immunity, agreed with Professor Sahli in thinking the future of serum-therapy in a chronic affection like tuberculosis to be at the least doubtful. Amongst the numerous products proposed for active immunisation Dr. Bernheim and Dr. Barlier treated only of the most important—those which had been the object of sufficient experimental and clinical researches. They devoted to each one a detailed study, examining one after the other their nature, their mode of preparation, their physiological properties, the doses and the methods of employment, the indications for their use and their dangers, and summarised their respective therapeutic value. They examined in succession the first tuberculin of Koch, the tuberculin T.R. of Koch, the bacillary emulsion of Koch, the filtered bouillon of Denys, the tuberculin of Maréchal, the tuberculin of Béraneck, and the tuberculin of Jacobs. From the comparative study of these different tuberculins they concluded that those which contained the toxins present in the bacilli themselves (tuberculins of Béraneck and Jacobs) possessed the most active immunising properties. They had not had occasion to experiment personally with Béraneck's tuberculin. As to the tuberculin of Jacobs the very numerous observations (amounting to hundreds) which they had collected in their anti-tuberculous dispensaries showed at the same time the perfect innocuousness of this product and its remarkable activity in the most different manifestations of the tuberculous infection. They considered that Wright's opsonic method allowed of the exact observation of the degree of immunisation of the organism, and would be "a precious guide in deciding the question of the doses to employ and their progressive elevation. Thanks to this method the employment of tuberculin is not an empirical treatment but it is founded upon a really scientific basis."

right in his surmise. That letter, on its way from the Silesian village, somehow got "delayed in transmission," and it was not till the March of this year that it reached its destination. Submitted to the Pope by his private secretary, it received immediate and kindly acknowledgment, accompanied by the Apostolic benediction and a present of a still greater sum than the largess of 1865—"Missâ simul summâ libellarum bis centum" (according to the "Vox Urbis"), or 200 francs in Italian, that is £8 in English money.

HARVEY'S PADUAN DIPLOMA.

THE Royal College of Physicians of London has issued a facsimile of one of the most interesting documents in its library—namely, the Diploma of the Doctorate of William Harvey which he obtained from the University of Padua, granted in the name of Count Sigismund de Capitibus Listae. Dr. J. F. Payne, the learned Harveian librarian, has written some explanatory notes and has thoughtfully provided a translation for the benefit of those whose recollection of the elaborate "periods" of the Latin tongue has become somewhat faint. Harvey entered the University of Padua in 1598 and his diploma is dated 1602, "Indictione Quintadecima." These two last words require some explanation. The indiction was a cycle of 15 years, and to find the year of the indiction the number 3 is added to the date and the sum is divided by 15. The quotient gives the number of cycles and the remainder, if any, the year of the indiction. In the present case 1602 plus 3 makes 1605, which divides exactly by 15 into 107. As there is no remainder the year is the fifteenth year of the cycle. So "quintadecima indictione" means "in the last year of the cycle," and not, as would at first appear, "in the fifteenth cycle." To return to the diploma: it is beautifully written in Roman lettering with important capitals and sentences in gold. The first page is illuminated all over with a floral groundwork, three little miniatures of landscapes, and at the top the "stemma" of a *conciliarius* of the Natio Anglica. The illuminations, which are admirably reproduced, show a sad falling off from the beautiful work of the Middle Ages. In the text Harvey is held up to admiration in a most fulsome way, but this style, as Dr. Payne shows, was common to most documents of the kind. The Latin is no longer the rather free, easy-going Latin of the Middle Ages, but built up into "periods" of the most classical form. Take the following one as an example, which is even better than that which Professor Postgate in his "Sermo Latinus" evolved for the instruction of youth from the well remembered sentence "Balbus murum aedificavit." Here it is, and in its stately roll we seem to see the red gowns of the doctors, the swords, and the pompous manners of the seventeenth century:—

> Nos Sigismundus Comes praefatus Imperiali Authoritate Familiae Nostrae antiquitus gratiose concessa ab Invictissimo felicis recordationis Sigismundo olim Rom. Imperatore semper Augusto, ac Germaniae, Ungariae, etc. Rege, prout amplissimo patet Privilegio, Sigillo Imperiali munito, dato Basiliae Anno MCCCCXXXIIII die tertia Aprilis, Nobilem et Eruditissimum D. Guglielmum Harveum, Folkstoniensem Anglum Illustris D. Thomae filium, Inclytae Nationis Angliae Consiliarium, Themata in Artibus et Medicina proposita per Magistros Excellentissimos Artium et Medicinae Doctores Dominos Hieronymum Fabricium ab Aquapendente Anatomen et Chyrurgiam publice profitentem, Io. Thomam Minadoum Rhodiginum Practicam Extraordinariam Medicinae in primo loco legentem; Julium Casserium Placentinum Anatomen, Physicam et Chyrurgiam exercentem; Georgium Raguseum Venetum Physicam Ordinariam in secundo loco declarantem; docte, eloquenter, laudabiliter, et excellenter pertractantem, Argumentis, Dubiis, et Casibus sibi propositis exquisite respondentem, et clare solventem cum ingenti animi voluptate audivimus.

It will be seen that there are here 125 words between the principal subject and the verb. The Royal College of Physicians, Dr. Payne, and the printers responsible for the reproduction are alike to be congratulated. The reproduction is a limited issue for Fellows only, who can obtain a copy on application, and his Majesty the King has been graciously pleased to accept a copy thereof.

TACTICS AND THE HEALTH OF THE ARMY.

TWO interesting and instructive articles which have appeared under the above heading in the last two numbers of the *Saturday Review*—viz., those for the 7th and 14th inst., by Field-Marshal Sir Evelyn Wood, V.C., are well worthy of the attention of our readers. The articles deal with events extending over a long period of time, from 1848 to 1908, and their value consists not only in the fact that they afford their author an opportunity of contrasting the earlier with the later period of our army history, but that they are also based upon the result of observations derived from a long personal experience of an exceptionally distinguished and varied nature. Like all stories worth the telling, the moral, if an old and oft-repeated one, lies on the surface. It shows how great have been the evil results of ignorance, prejudice, and a mistaken official parsimony in the past management of our wars, and it also shows how much has been already accomplished, and what is still to be hoped for and may potentially be achieved, by the application of sanitary science and preventive measures in war. The articles may be usefully read *in extenso* by medical officers and others interested in the subject, for they do not readily lend themselves to any brief summary. But, speaking generally, it may be said that the improvements that have taken place in the health of the army have for the time being followed upon, and been just in proportion to, the influence, independence, and efficiency of its medical service. Field-Marshal Sir Evelyn Wood in a concluding paragraph says:—

> I am convinced from my experience of 30 years as a general that the army doctors should be regarded not merely as healers of sick and wounded, but as trusted staff officers to advise their chiefs how to guard the troops against the originating and spreading of disease, and thus maintain the numbers of effectives in a campaign. This will result not only in the increasing of fire effect, but will raise immensely the fighting value of the troops and will incidentally enable us to reduce the costly and cumbersome hospital establishments and transport.

A PROCESS FOR THE PRESERVATION OF DEAD BODIES.

WE have recently had sundry documents submitted to us concerning a process whereby dead bodies can be preserved from decomposition for an indefinite time without the removal of any viscus and without any elaborate technique. The process was introduced by Cav. Chiarella and has the warm support of Professor Guido Baccelli and Dr. A. Severi, professor of forensic medicine in the University of Genoa. In March of this year Dr. Severi delivered a lecture on the process in the Anatomical Institute, Genoa, before the newly made graduates in medicine. Dr. Severi began by giving a short account of the processes involved in decomposition and of the various means by which this may be prevented. He gave a description of methods of embalming both ancient and modern, and then proceeded to describe that adopted by Chiarella. He employs lysoform, a combination of a potash soap with formaldehyde. The vessels are first washed out with the fluid and in some cases lysoform is injected into the abdominal cavity. Besides this Chiarella finds it of value to immerse the body in the lysoform for from 24 to 70 hours. Dr. Severi at his lecture demonstrated a body preserved by the Chiarella method in September, 1907. He pointed out that the skin was yellowish in colour and of a leathery consistency, but that the hair was normal and could not be easily pulled out. On the thoracic and abdominal cavities being opened there was no odour of putrefaction and the viscera were of normal colour and consistency. In much of the alcoholic precipitate of Koch's old tuberculin to produce the same effect. Tuberculin CL was well borne by patients and the results had been good in increasing resistance and delaying the process of tuberculosis, though it was no more a cure than was any other similar substance. Very small doses, 1-1000th milligramme, must be used at the commencement until ultimately 3-10ths of a milligramme might be administered. A reaction exceeding half a degree C. was avoided by maintaining the intervals of from 10 to 12 days between the injections. Professor Calmette also strove to obtain a constant increase of the opsonic index. When studied experimentally *in vitro* tuberculin CL showed an affinity for the lipoids constantly present in the serum of tuberculous men and cattle. These substances were probably lecithins. In this connexion Professor Calmette alluded to his researches upon the activation of cobra-venin by the free lecithin of serum. Hence tuberculin CL afforded an index of the affinity of the patient's serum for the products of the tubercle bacilli, and this gave a valuable means of controlling medication by tuberculin, hitherto a most difficult matter.

The Bio-chemistry of the Tubercle Bacillus.

On the same day the biological chemists gathered in force and presented a series of papers upon the proteids of the tubercle bacillus, its immunising substances and enzymes, and upon the chemistry of the body during infection.

Dr. **Vaughan** (Ann Arbor) described his method of separating poisonous substances which would kill an animal in a few months in doses of from 75 to 100 milligrammes. The non-poisonous residue sensitised to the tubercle bacillus and was now being used in human cases of tuberculosis. It was yet too early to compare this method with older ones.

Dr. **Noguchi** (Japan) communicated through Dr. **Simon Flexner** (New York) a lengthy study upon the action of soaps upon the vitality and immunising property of the bacillus tuberculosis. They were led to try this by the bactericidal activity and the complementary action of oleate soaps in conjunction with blood serum. They concluded that oleate soaps modified tubercle bacilli so that when subsequently inoculated into guinea-pigs they either failed to produce lesions or caused slighter ones than those shown by the control animals, with the result that death was postponed. These animals had acquired an immunity to virulent cultures, and either developed no lesions or far milder ones than did the control animals. The bactericidal effects of these soaps could not be reproduced by their component acids and bases. Dr. Noguchi believed that these lypoids were probably among the products of autolysis of lymph gland tissue which had been shown to be injurious to the bacillus tuberculosis by Conradi and Bartel.

Another paper from the Rockefeller Institute was that of Dr. **Eugene L. Opie** (New York), who had studied the enzymes of tuberculous tissue produced by inoculating the pleura. He found that the polynuclear leucocyte enzyme quickly diminished in activity after his inoculations. A second enzyme occurred in great abundance, only disappearing when caseation supervened. It digested proteid in weak acid media and it was probably derived from the epithelial cells of the exudate. These enzymes were inhibited by blood serum but not by that of the pleural exudate. Dr. Opie therefore believed caseation to be due to an autolysis by these enzymes when, through diminution of the vascular supply, they were no longer inhibited.

Dr. **von Schrotter** (Vienna) reported an atttempt by Reitter and Stoerk to devise a means for the Diagnosis of Tuberculosis by a Serum Reaction. It consisted of a modifi- cation of the well-known method by carbolised sodium chloride. The precipitation of the colloids occurred in a higher percentage when an ethereal extract of tubercle bacilli was added to the solution in the proportion of ½ grain bacilli to 200 cubic centimetres of solution. In applying the method care must be taken to exclude such lipæmic conditions as diabetes, tumours undergoing regressive metabolism, and occa- sionally non-tuberculous infections. The method accordingly required confirmation by further trial.

A most valuable contribution to this subject was that of Dr. **Paul Courmont** (Lyons) upon the Agglutinating Power in Tuberculous Patients, with reference to Serum Diagnosis and Prognosis. He emphasised the indispensa- bility of rigorous technique regarding choice of culture, its method of preparation, and the nature of the reaction in accordance with age and species, and he warned against its interpretation without coördination with the clinical symptoms. In suspicious cases positive reaction had great value. The information might be (1) general, where the information derived from it was equal to that of the conjunctival or cuti-reaction; but it did more, (2) for by testing the agglutinating power of serous effusions it assisted in locating the tuberculosis. The indication for prognosis was derived from the measure of agglutinative power, which was in inverse ratio to the virulence of infection. It was lacking in serious and advanced cases and increased during improvement.

Dr. **Ishigami** (Osaka) followed with a paper in which he claimed to have succeeded in preparing two remedies of comparatively great efficacy and free from any detrimental reaction: (1) tuberculin-toxoidin, a chemical preparation from tubercle bacilli, suitable for incipient and apyrexic cases; and (2) an immunising serum for advanced cases. The former was used by injection in progressive doses. Under this treatment the body-weight and vital capacity increased, the bacilli broke down and agglutinated, the opsonins increased, and early cases were completely cured in from three to six months, and later cases also when the general nutrition was good; recurrences were rare. Statistics were given showing that the average number of injections required was 65. By the use of tuberculin-toxoidin in animals he had obtained an immunising serum which no longer caused the characteristic troublesome reactions in patients, and he claimed to have cured three cases of comatose cerebral meningitis with this serum.

Dr. **Croftan** (Chicago) presented an abstract of his studies on the Calcium Metabolism in a Case of Tuberculosis. He believed that the increased urinary excretion of calcium was due to its affinity for the deutero-albumose present in tuberculous foci, sputum, blood, and urine. This was a protective reaction, for experiments showed that the "pyrogenic" effects of this albumose ceased when it was combined with calcium. The therapeutic possibilities of this were indicated by a seeming immunity amongst workers in lime salts.

Dr. G. **Bernheim** and Dr. P. **Barlier** (Paris) presented a joint report upon the Therapeutical Value of Tuber- culins. This was opened by a comprehensive historical survey of the search for a specific remedy for consumption the world over, and was followed by a consideration of the therapeutic value of the various active and passive methods of producing immunisation which had been proposed. As regards passive methods, Dr. Bernheim and Dr. Barlier, relying upon the recent works of Bordet on immunity, agreed with Professor Sahli in thinking the future of serum- therapy in a chronic affection like tuberculosis to be at the least doubtful. Amongst the numerous products proposed for active immunisation Dr. Bernheim and Dr. Barlier treated only of the most important—those which had been the object of sufficient experimental and clinical researches. They devoted to each one a detailed study, examining one after the other their nature, their mode of preparation, their physiological properties, the doses and the methods of employment, the indications for their use and their dangers, and summarised their respective therapeutic value. They examined in succession the first tuberculin of Koch, the tuberculin T.R. of Koch, the bacillary emulsion of Koch, the filtered bouillon of Denys, the tuberculin of Maréchal, the tuberculin of Béraneck, and the tuberculin of Jacobs. From the comparative study of these different tuberculins they concluded that those which contained the toxins present in the bacilli themselves (tuberculins of Béraneck and Jacobs) possessed the most active immunising pro- perties. They had not had occasion to experiment per- sonally with Béraneck's tuberculin. As to the tuberculin of Jacobs the very numerous observations (amounting to hundreds) which they had collected in their anti-tuberculous dispensaries showed at the same time the perfect innocuous- ness of this product and its remarkable activity in the most different manifestations of the tuberculous infection. They considered that Wright's opsonic method allowed of the exact observation of the degree of immunisation of the organism, and would be "a precious guide in deciding the question of the doses to employ and their progressive elevation. Thanks to this method the employment of tuberculin is not an empirical treatment but it is founded upon a really scientific basis."

express his opinions in general terms. There was a widely spread feeling that of all the neuroses insanity was the one most likely to reappear as the result of parental defect. He at once admitted that a very large amount of mental disorder was connected in one way or another with parental weakness, and therefore some things which were abnormal might appear in the offspring. He would propose to modify that somewhat later. The first difficulty lay with the general idea that all insanity was one—that, in fact, it was a disease. But, as was pointed out many years ago, insanity was not a disease, it was simply a negation. He believed strongly in the power of transmitting from parent to offspring tendencies to mental disorder. But the transmission was rarely what might be termed true—i.e., it was not common for the same form of mental disorder to appear in both parent and child. It was necessary to say that there were many branches to the neurotic tree and other conditions besides heredity were efficient causes in developing the form of disorder. The offspring of certain insane persons might develop epilepsy, megrim, and immoral or criminal tendencies, or be simply feeble-minded. Some forms of inherited mental weakness might be regarded rather as a reversion of type of mind. But they were very uncertain guides; the patients themselves were ignorant or unwilling witnesses, the friends were unwilling and certainly untrustworthy. Notwithstanding that he gave certain statistics which were more or less trustworthy; as trustworthy as any which could very well be obtained. From the last report of the Commissioners in Lunacy (1907), among the private patients under care, 19·6 per cent. of the men and 26·7 per cent. of the women were supposed to have hereditary neuroses. The numbers among the paupers were rather greater. Of the residents in Earlswood Asylum, 35·3 per cent. had a bad or nervous history. Among the children at the epileptic school colony at Lingfield the visiting physician gave 65 per cent., which he thought below the truth; but many of the children being foundlings no history had been obtainable. Dr. H. Ashby of Manchester found among the mentally defective that 75 per cent. had neurotic progenitors. He (Dr. Savage) believed that certain types of mental disorder owed more to hereditary disposition than to others. For general purposes he could divide the insanities which he was considering into those due to neuroses and those due to toxins. There were probably connecting links; the more excitable persons showed the disorder earliest. Rarely in his experience did anything like transmission of similar delusions occur. At the worst it was the few who showed insanity. Occasionally one met with a family of dumb mutes or idiots, the whole family being affected, and in such cases he had not been able to trace real insanity to the parents. The union of certain chemical bodies produced bodies totally different from the constituents of either, and so it seemed to be in the case of man and woman. The variations arose from types and conditions which at present were not understood. In the case of the insane or the highly neurotic there was such a thing as breeding-out. He had seen cases in which grave mental disorder in one generation had been represented in later generations by tricks of muscle or moral faults and in another generation by simple eccentricities or even brilliancy. The commission which recently reported on the condition of the feeble-minded devoted much time and attention to the question of hereditary predisposition. It concluded that feeble-minded parents might have both normal and feeble-minded children; that in many cases an originally feeble-minded person who perhaps started a line of feeble-minded descendants was not a descendant from a neurotic parent at all but was rather a reversion. His own view was that the mental disorder arising from toxins was not likely to be reproduced in the next generation, except under special conditions. For instance, a child who was begotten at the time the father had marked general paralysis of the insane was an idiot, whereas children born before the full development of the general paralysis in the father were healthy. An important thing to remember was the tendency of certain diseases to skip a generation. It was certainly met with in insanity. Yet skipping seemed to be comparatively rare. There were certain families in which there was most certainly power to transmit tendencies to insanity, and there seemed, as Sir William Gowers had pointed out, a transmission of bodily conditions such as arterial degeneration, which might be evidenced by apoplexy. There were many people who lived to a good age, but their death took place mentally first. He had known a woman coming from an insane stock who during 40 years in an asylum had more than a hundred attacks of acute mania, yet who in the interval was bright and showed no evidence of mental decay. It seemed that if a person was to become insane the chances of temporary recovery at all events seemed to depend to a great extent upon an inherited neurosis. He could not altogether pass over reference to what were called toxic insanities. It was possible that the neurotic were specially liable to exhibit nervous conditions under favouring circumstances. In a neurotic subject influenza certainly could precipitate an attack of insanity or emotional disturbance. The toxic disease which was of most interest was at present general paralysis of the insane and he felt considerable difficulty in that regard. The number of general paralytics with a neurotic inheritance was quite small, yet the returns from some observers had been very considerable. There were, as he had tried to point out, certainly links in the neurotic chain as seen in the offspring of the insane and of the highly neurotic, but he did not look upon inheritance as a tyrant with inflexible power which drove the offspring to destruction, and he did not think that because the fathers had eaten sour grapes therefore the children should necessarily have their teeth set on edge. There was, in his opinion, power to transmit acquired peculiarities, yet the tendency to transmit predisposition might be modified by surroundings.

Dr. F. W. MOTT said that he did not expect to be called upon yet to speak in the debate, and therefore he had no precise data to lay before the meeting. He had been engaged in an interesting research which had some peculiar bearing on the subject—namely, in order to see if the convolutional pattern showed a resemblance amongst relatives, such as their physiognomies so often do. The cases which were supplied to him from the London county asylums he had sent on to Mr. Schuster of Oxford, who was photographing and describing them. He sent papers to the different asylums, and the returns came back with comparatively few relatives. But he found that some of the relatives were at other asylums. As a matter of fact a big snowball had formed and it was getting bigger every day and one was now struck with the number of relatives in asylums. That was a fact of considerable importance because it was difficult to get hereditary histories from such people. He had obtained some very remarkable histories and some of them seemed to show what Professor Bateson had indicated, that it was almost impossible to trace insanity. He had instances of three and four generations of suicides with insanity in the family. Practically all the people in the family were insane. He had an instance of a whole family of insane men and women admitted into Colney Hatch Asylum of whom the father was a drunkard, and that had been copied into most of the temperance books notwithstanding that in the same passage he had given instances of people who were strict total abstainers, and yet all their three children suffered from adolescent insanity. On tracing them out there was found to be insanity in the collateral branches. Later he hoped to be able to present some interesting statistics concerning the relatives. There were some types of insanity which were especially prominent, such as dementia præcox. They were said to furnish a large number of cures, but they kept returning periodically. They were not anti-social, and therefore were considered to be cured. 80 per cent. of the cases of adolescent insanity could be shown to have an hereditary history. So far as he had gone, general paralysis was not common; he had found only a few cases in 100. When met with it usually had been general paralysis in the father and general paralysis in the daughter or the son, and in those children one generally found signs of hereditary syphilis. Therefore he looked upon general paralysis as essentially due to syphilis. That general paralytics showed so little signs on the body was one of great interest. When syphilis affected a whole race he thought there was a certain amount of immunity, but that was at the expense of throwing out antitoxins which were neutralised. And the recent researches which resulted in the finding of antibodies in the cerebro-spinal fluid in practically every case suggested that the nervous system wore itself out in throwing out those antibodies which would neutralise the effect of the conditions valuable animals the Bang method.—The tagging system, too, was advocated by Dr. ROGERS (Kansas), who pointed out that metal ear tags with the address of the original owner of swine sent to slaughter-houses would enable the health officer to locate automatically the centres of tuberculous infection among cattle.

Dr. DYSON (Chicago) drew attention to livestock journals and breeders of pedigree stock as well as the organisers of expositions and fairs. All of these, for financial considerations, he said, "attempt to discredit the accumulated knowledge of time and a host of pioneers in the field of research and experiment with reference to the efficiency of tuberculin as a diagnostic agent, when properly administered."

Dr. POPE (New Jersey) submitted the farmers' point of view; and after explaining the causes of their hostility or indifference, and discussing the incidence of the cost of stamping out tuberculosis, advocated the fixing of a time limit after which the cost of compulsory destruction should no longer rest upon the State but upon the careless individuals. In this way a stop would be put to the present increase of tuberculosis among domestic animals which was now occurring in spite of its decline among human beings.

Dr. WARD (San Francisco) showed how, in spite of the open-air life led by dairy cattle in California, about 30 per cent. of over 1000 cows reacted to tuberculin and that 82 per cent. of the herds were infected. The correspondence of this result with the figures found in New York State, where the conditions as regards stabling were so different, showed that even the mild climate and out-of-door life had not counteracted the unskilful handling which permitted of this amount of disease.

The investigation of Dr. DALRYMPLE (Louisiana) into the conditions of 12 Southern States showed that the prevalence and increase of tuberculosis were almost wholly among stabled cattle, and that the native cattle were practically free although there was practically no legislation dealing with tuberculosis in cattle. In his own experiment station there had been no cases since the herd was tested and the diseased animals were eliminated 10 years ago.

Dr. MOHLER and Dr. WASHBURN (Washington) reviewed the recent investigations of the United States Bureau of Animal Industry and declared their resulting belief that the bovine, human, and avian types might interchange characters in favourable conditions in other hosts. They claimed that they were the first (in 1896) to differentiate the bovine type.

Dr. SCHROEDER (Maryland) drew attention to the intermittent passage of tubercle bacilli per rectum in about 40 per cent. of cattle apparently healthy, which, however, had reacted to tuberculin. Two years' observation of these animals doubled the percentage in which at one time or another organisms were found in the fæces. As it was rare to find commercial milk free from fæcal contamination and as a great deal of mixing occurred in the dairies it was certain that a wide distribution of bovine bacilli insured their introduction into human beings.

Dr. HESS (New Jersey) stated that by inoculation he had found that 16 per cent. of samples of New York milk contained tubercle bacilli.

The problem of control was discussed by Dr. REYNOLDS (Minnesota), Dr. HUGHES (Cornell), Dr. KLEIN (Pennsylvania), Dr. MARSHALL (Philadelphia), and Dr. MOORE (Ithaca), and great stress was laid upon the value of tuberculin. In this section, too, researches upon the dermo-reactions were presented by Dr. LIGNIÈRES (Argentina), Dr. MOUSSA (Alfort), and Dr. MANTUX (Canne le Cannet), and upon the ophthalmic reaction by Dr. BELLART (France) and Dr. WHITE and Dr. CAMBELL (Ohio). These results were confirmatory of those established in human beings.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

University News.

THE Huxley lecture is to be delivered this year by Professor Ronald Ross who will give an address on malaria on Nov. 25th. His subject is one that has great interest for the medical profession and the demand for seats will probably exceed the capacity of the hall in which the lecture will be given. Professor A. Bostock Hill has resigned his lectureship in toxicology which he held in association with his chair in public health and the vacant appointment has not yet been filled; but the vacancy caused by the resignation of Mr. George Heaton, the assistant to the chair of surgery, has been filled by the appointment of Mr. Leonard P. Gamgee who is one of the assistant surgeons at the General Hospital.

The Medical Inspection of School Children.

At the annual meeting of the Midland branch of the Society of Medical Officers of Health recently held in Birmingham the President, Dr. Reginald Green, summarised the results which had been obtained in King's Norton, where he is medical officer. He stated that a systematic test of the eyesight of 7412 children revealed defects in 1140 cases. The time taken in the examination of the cases was necessarily considerable, but the difficulties of the work were greatly exceeded by the trouble which was incurred in attempting to get the defects remedied, for it was found that only 11 per cent. of the parents communicated with had provided the necessary spectacles after a reasonable lapse of time. The general examination of the children revealed that 71 per cent. had defective teeth, 28·7 per cent. enlarged tonsils, 19 per cent. verminous heads, 10 per cent. some amount of lateral curvature of the spine, and external eye disease was present in 7 per cent. During the course of the meeting the large amount of work which is being thrown upon local hospitals, as a result of the inspection of children, was referred to and it was suggested that the education authorities should contribute to the local hospitals. This suggestion is one of the natural results of the Act, and the question it leads to, that of the nationalisation of hospitals, will become more prominent and pressing as the work of inspection is carried on and elaborated. The results of the examination at Smethwick differ somewhat from those obtained in King's Norton, judging from the interim report presented by Mr. W. F. Marsh Jackson, the chief medical inspector. The total number of children inspected was 2939, and of these about 10·5 per cent. had defective vision, 15·6 per cent. defective teeth, 4·1 per cent. defective hearing, and 8·3 had enlarged tonsils. 100 congenital deformities were noted, including 11 cases of lateral curvature of the spine, and eight children were mentally deficient. The condition of the children's hair, especially that of the girls, was bad, otherwise bodily cleanliness was generally good, and only 15 cases of skin disease were noted. Up to the present the education committee has taken no official action with regard to the treatment of sickness and physical disability, but the Children's Hospital Benevolent Fund had enabled letters for the Birmingham Eye Hospital to be given to special cases.

The Adult Cripples' Guild.

An earnest appeal is being made by Sir Hallewell Rogers for increased financial support for the Adult Cripples' Guild. The objects of the guild must appeal to all: they are to find situations for those who can go out to work; to teach handicrafts to those who cannot go out and to dispose of the work done; and to obtain from the hospitals the best medical advice and to help to get the instructions carried out. Lack of funds is at present interfering with most of the objects, and it must be sincerely hoped that the income of £203 7*s.* 3*d.*, which was all the guild obtained in 1907–08, will be considerably increased this year.

The City Analyst's Report.

The last quarterly report of the city analyst (Mr. J. F. Liverseege) is distinctly favourable as it appears to indicate a decided diminution of the adulteration of foods. 458 samples were taken and examined under the Sale of Food and Drugs Act and only one was adulterated with preservatives and only 5·7 per cent. of the samples were adulterated in other ways than by preservatives. Both these results are distinctly better than in previous third quarters. Only 13 of 189 samples of milk contained less than 11·5 per cent. of solids and only one sample contained boric acid. In two cases in which samples of milk were deficient in fat it was found that the cows were only being partially milked, the remainder being left for the calves, and when samples of the "fore milk" were analysed they were proved to contain only 1·7 per cent. and 1·8 per cent. of fat respectively, from which it on the Court of Examiners and the PRESIDENT stated that the vacancy thus occasioned would be filled up at the next ordinary meeting of the Council on Dec. 10th.

Mr. A. W. Mayo Robson was elected the representative of the College on the Court of Governors of the University of Sheffield.

The PRESIDENT reported that the Bradshaw lecture would be delivered by Sir W. Watson Cheyne, Bart., C.B., on Friday, Dec. 4th, at 5 P.M., and that the subject of the lecture would be the Treatment of Wounds.

MEDICAL MEN AND MUNICIPAL HONOURS.

THE following is a list of members of the medical profession who have been elected or re-elected to the mayoral chair, together with brief notes of their medical and municipal careers so far as we have been able to ascertain them.

Aldeburgh.—Mrs. Elizabeth Garrett Anderson, M.D. Paris, L.S.A., is the first lady mayor to be elected since the passing of the Act in 1907, which admitted women to town councils. She obtained the L.S.A. in 1865 and graduated in the University of Paris in 1870. In 1866 she became senior physician to the New Hospital for Women and subsequently consulting physician. She was also dean and lecturer on medicine at the London School of Medicine for Women and visiting physician to the East London Children's Hospital.

Brecon.—Mr. George Philip Francis, L.R.C.S. Edin., L.A.H. Dub., J.P., who has been re-elected the Mayor of Brecon, was born in 1855, being the only son of the late Mr. C. Francis, J.P., of Vennyfach, Brecon. He received his medical education at St. Thomas's Hospital, taking the qualifications of L.R.C.S. Edin. and L.A.H. Dub. in 1879. Mr. Francis commenced practice at Bourton, Dorset, and continued there until 1887 when he succeeded to the practice of Mr. Talfourd Jones at Brecon. Mr. Francis is surgeon to the Brecon Infirmary and medical officer of health of the Merthyr Cynog district of the Brecon rural district council; he is also medical officer to H.M. Prison and to the post office at Brecon. Mr. Francis was elected to the town council unopposed four years ago. He is a prominent Freemason, a keen sportsman, and a successful breeder and judge of hackney horses.

Berwick-on-Tweed.—Mr. Charles G. Maclagan, M.B., C.M. Edin., the mayor of Berwick-on-Tweed, graduated in Edinburgh in 1883 and subsequently commenced practice at Berwick-on-Tweed. He is an Admiralty surgeon and agent, surgeon-lieutenant in 7th Battalion Northumberland Fusiliers, and surgeon-major in the Army Reserve. He is district medical officer for the town of Berwick, and medical officer of the union workhouse. He entered the town council in 1897 and was sheriff in 1903-04. He was chairman of the school board from its formation until its abolition by the late Education Act. He was also chairman of the education committee of the town council and of the public health committee.

Conway.—Mr. Morgan John Morgan, L.R.C.P. & S. Edin., the mayor of Conway, was born in Waenfawr, near Carnarvon, in the year 1864. After being educated at Clynnog and Aberystwyth and finishing his preliminary studies he commenced his medical curriculum at Edinburgh in the year 1882. His career as a student was marked with success and he qualified in 1886. After spending two years as assistant in the large quarry district of Blaenau Ffestiniog he commenced a practice in Conway in 1888. Soon after this date he was elected unopposed as member of the town council, being then only 24 years of age. During the 19 years that he has been a member of the council he has taken a prominent part in the public life of the town and county. He has rendered signal service to the ratepayers in advocating a pure water-supply for the town. He has twice occupied the mayoral chair—in the years 1898-99 and 1900. In the latter year he had the honour of entertaining the Prince and Princess of Wales, then Duke and Duchess of York. For some years Mr. Morgan has been the leader of the Liberal party in the town and is chairman of the Conway Liberal Club.

Eye.—Mr. Edgar George Barnes, M.D. Lond., M.R.C.S. Eng., L.S.A., the mayor of Eye, who was born in 1848, received his medical education at St. George's Hospital. In 1869 he qualified as a Licentiate of the Society of Apothecaries, and in 1870 became a member of the Royal College of Surgeons in England. In the same year he graduated M.B. at the University of London and took honours in obstetric medicine. In 1873 he took the M.D. degree of his University. Since 1869 he has been engaged in general practice in Eye. He has held the appointments of medical officer of health of the borough of Eye and of the Hartismere rural district council since the passing of the Public Health Act, 1872, by which these offices were first created. For many years he has been a justice of the peace for the borough of Eye and chairman of the governors of Eye Grammar School. In 1882-83 he was president of the Norwich Medico-Chirurgical Society and from 1889 to 1901 he was secretary of the East Anglian branch of the British Medical Association, having been president of the East Anglian Branch of the British Medical Association in 1888.

Finsbury.—Mr. William Alfred Dingle, M.D. St. And., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., has been a member of the borough council of Finsbury for the last three years and is medical officer to the Holborn board of guardians. He is surgeon to the Houseless Poor Asylum and Surgeon-Major East London Royal Engineers (Territorials) and Army Medical Reserve. He is surgeon to the St. Luke's parochial charities and medical officer to the Linen and Woollen Drapers' Institute; a Fellow and Vice-President of the Hunterian Society, and member of council of the Volunteer Medical Association. In 1878 he contributed to THE LANCET an article entitled "Nitrite of Amyl in Sea Sickness." He has travelled a great deal and his knowledge has proved of considerable use on the public health committee of which he has been a member since his election to the council. His choice for the mayoralty was a unanimous one.

Kingston-on-Thames.—Mr. William Evelyn St. Lawrence Finny, M.B., M.Ch. R.U.I., L.R.C.P. Edin., received his education at St. Columba's College and Trinity College, Dublin. He graduated at the Royal University as M.B. and M.Ch. in 1887 and as B.A.O. in 1891. In 1897 he became a Licentiate of the Royal College of Physicians of Edinburgh and also obtained the L.M. Rotunda, Dublin, with special certificate in gynæcology. In 1891 he took up general practice at Kingston Hill and seven years later was elected to the town council and was chosen as mayor. Dr. Finny, who is an archæologist, was fortunate in being mayor at the time when the 700th anniversary of the granting of the first charter to the borough by King John was celebrated, and he designed a stained-glass window for the town-hall as a memorial of that occasion. He was re-elected mayor for the Coronation Year, 1901-02, and as mayor was present in Westminster Abbey at the King's Coronation, and received King Edward VII.'s Coronation medal. He also took a leading part in the celebration of the 1000th anniversary of the coronation of Edward the Elder at Kingston in 1901 and designed another memorial window for the town-hall. He was re-elected mayor for the third time November, 1908-09. Since joining the town council he has served on the sanitary and other committees. He is a member of the council of the Surrey Archæological Society and a justice of the peace for his borough.

Leicester.—Mr. Charles Lakin, L.R.C.P. Edin., L.F.P.S. Glasg., the mayor of Leicester, is a native of Nottingham and went to Leicester 50 years ago and for many years has been a highly respected member of the medical profession in the town. He became a member of the Leicester town council 23 years ago, and 16 years since was elected an alderman. During the whole of his connexion with the council he has been a member of the sanitary committee, the asylum committee, the library committee, and the water committee. On the sanitary committee he has distinguished himself by devotion to duty and his experience and ability have made his services invaluable. Leicester's new mayor has the reputation of being a man of independent thought and action.

Montgomery.—Mr. Nicholas Watson Fairles-Humphreys, M.R.C.S. Eng., L.S.A., who has been re-elected Mayor of Montgomery, was born in 1837 and was educated at St. Bartholomew's Hospital. In 1885 he was elected alderman for the borough of Montgomery and has been seven times mayor of that borough. He is a justice of the peace for the county of Montgomeryshire, was high sheriff in 1882-83, and has been a county alderman since 1889. His grandfather, Nicholas Fairles, justice of the peace for

Sir G. H. Philipson is appointed to the honorary colonelcy of the Royal Army Medical Corps of the Northumbrian Territorial Division. I congratulate the venerable professor of medicine of the University of Durham on his acceptance of an appointment in the Territorial Army and hope that his example will stimulate younger men to take their part also in the Territorial organisation.

Eye Department of the Royal Victoria Infirmary.

At the monthly meeting of the governors of the Royal Infirmary held recently Dr. T. Gowans was elected honorary assistant in the eye department. Dr. Gowans already holds the appointments of honorary ophthalmic surgeon to the Ingham Infirmary, South Shields, and to the South Shields Dispensary.

The Coronership of Newcastle.

In my last letter I referred to the fact that the Newcastle Ratepayers' Association had approached the members of the city council individually by letter deprecating the practice of members of a public body becoming candidates for appointments in their own gift. Letters inclosing copies of this circular were also forwarded to the Local Government Board, the Registrar-General, and several Members of Parliament having associations with the North of England. The Local Government Board replied that it had no control over local authorities in the matter of these appointments. There were originally 12 applicants for the coronership but an unusual situation arose the day before the council was to meet to make the appointment when the following letter was received by the council signed by 11 of the applicants withdrawing their applications :—

> GENTLEMEN,—In response to the advertisement issued by your council on the 22nd ult., inviting applications for the office of coroner, we, the undersigned, became candidates for the post. We now find, however, that a majority of the council had then already promised to vote in favour of a certain councillor Under such circumstances we feel that it is quite useless for us to proceed with our candidature and therefore withdraw our applications.

When the council met there was, therefore, but one applicant, who, at the time of the death of the late coroner, was a councillor and vice-chairman of the watch committee. A motion to postpone the election for three months was negatived by 49 votes to 17 and the applicant was appointed by 50 votes to 16.

Day Nursery in Newcastle.

Recently Mrs. Woods, the wife of the High Sheriff of Northumberland, opened a day nursery which has been established in the city through the generosity of the Lord Mayor, Mr. W. J. Sanderson. The nursery is intended as a place where poor women who have to go from home during the day to earn their living may leave their infants while they are at work, with the assurance that they will be properly cared for during their absence. The Newcastle institution is to be affiliated with the National Society of Day Nurseries. Subscriptions and donations are invited towards meeting the cost of maintaining this excellent institution, and in view of the interest now being taken in the preservation and protection of infant life there will, it is hoped, be no difficulty from the financial point of view.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Clinical Teaching in Edinburgh.

THE feeling has been steadily gaining strength in Edinburgh that the time has come when radical changes ought to be made in the medical curriculum. This recently found expression in a discussion which was initiated by the Pathological Club and culminated in the appointment of a committee to go into the whole question and to report. That report is being waited for, but meanwhile it is understood that an important question bearing upon clinical teaching has arisen or is shortly to arise. In this connexion it may be mentioned that some time ago the University proposed that all the full surgeons to the Royal Infirmary should become University lecturers on clinical surgery and that for certain privileges offered by the University the lecturers should pay the University a proportion of the fees collected from students. The offer was rejected for various reasons. It is understood that the matter is to be opened again and that probably the University will offer terms that may be more acceptable. Whatever decision the surgeons may come to it is certain that, as has been said, there is a growing feeling that changes must be made and that amongst the most clamant are changes in clinical teaching. At the present time, as in the past, the students may select any one of five teachers in clinical surgery, two of whom are professors and three are extra-mural. The result is that the students are badly distributed and there is no attempt at coördination of teaching amongst the lecturers. Such a want of arrangement may have served well enough in the past but it is not in accordance with what is justly looked for in the training of the medical student of to-day. When this matter was referred to on the previous occasion it was noted that the University had made the proposals, although in all medical matters the tendency on the side of the University is towards conservatism, and that the rejection of the proposals came from members of the extra-mural school. The University might be more successful if it frankly acknowledged that the proposals are made with a view of strengthening the University rather than as a concession or a privilege offered to the extra-mural school. The extra-mural school in Edinburgh has always held its own and taken quite its own share, if not more, of the students and of the teaching. Financially such coordination of the teaching would not benefit the extra-mural lecturers, but were they appealed to on the higher and wider ground financial considerations would almost certainly be given a secondary place.

Women Graduates and the University Franchise.

Much interest was aroused in Edinburgh last week by the report of the proceedings in this case before the House of Lords. Two of the women graduates argued their own case, Miss Jessie Chrystal MacMillan, B.Sc., speaking for three hours in expounding the views held by her and the other appellants. Their lordships evidently treated them with much consideration, allowing them to continue to speak without interruption save by an occasional question or comment. Miss MacMillan's speech contained many points of much historic interest and seems to have been characterised by much lucidity of expression. The Lord Chancellor had to remind Miss Frances Helen Simson who followed Miss MacMillan that they were a judicial body and that what they had to discuss and to consider was the meaning of the Act of Parliament and the real interpretation of the law. Their lordships' judgment is awaited with interest.

The Royal Medical Society of Edinburgh.

At Melbourne-place, Edinburgh, on Nov. 13th, Dr. John Gilmour delivered his presidential address before the society. He chose as his subject the surgery of 100 years ago, describing, in the course of a very interesting address, many methods of treatment then employed for the relief of various surgical conditions. He made special mention of the life and work of William Hey. Dr. Barcroft related a case of posterior basic meningitis which was treated with great success by the use of a specific serum, opportunity being taken of a lumbar puncture to inject the serum through the same needle. Dr. F. E. Reynolds showed two very characteristic cases of congenital specific disease.

Graduation Ceremony at the University of Glasgow.

The autumn graduation ceremony took place last week. The Principal, Sir Donald MacAlister, received an ovation from the students on account of his recently acquired K.C.B. In the faculty of medicine the only graduands were those who had been up for the M.D. examination. Of 13 who received the degree two graduated with honours and five with commendation.

Gartloch Asylum.

In the annual report recently issued of this asylum it is stated that 300 cases were admitted, while 294 were discharged or died during the year. There were in all 1040 persons under care during the year and the average number resident was 752. The character of the admissions during the year was bad from the point of view of probable discharge or recovery. Of those admitted with a history of the duration, 186, or 64 per cent., were ill over a year on admission, were congenital imbeciles, or had been ill previously. There were 15 epileptics admitted, 34 general paralytics, and 52 cases of dementia (secondary, organic, or senile), besides paranoiacs and other cases of chronic registered person, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine and surgery, or an apothecary may, upon a summary conviction for any such offences, be fined a sum not exceeding £20 (Act of 1858, s. 40).

Demanding Money by Menaces from a Medical Practitioner.

At the recent sessions at the Old Bailey Mr. Justice Bigham passed a sentence of seven years' penal servitude upon a labourer, 29 years of age, giving the name of George Sims, and living at a Rowton House, who was indicted for demanding money with menaces from two different gentlemen. The first of these was a medical practitioner practising at Highgate; he was a stranger to the prisoner, and being threatened in a letter with exposure of some kind in the newspapers unless he sent the writer the sum of £500 he placed the matter in the hands of the police, who are to be congratulated on their success in bringing the offender without delay to justice. This was, no doubt, an attempt at extortion of so stupid and aimless a kind that no sensible man need have been seriously alarmed by it, but such an incident must always cause trouble and anxiety to some extent, and medical men should note the attack made on a brother practitioner on account of its very groundlessness and because they are peculiarly likely to be the target of the swindling mendicant, the blackmailer, or of anyone else to whom it is of importance to ascertain names, addresses, and all other details possible with regard to persons of respectable position likely to prove suitable victims. In this connexion we quote a statement made by the convict Sims after his arrest. He said to the police who had told him that his handwriting in the letters which he had written had been identified: "Its no use denying it. I did write them in the Free Library in the New Cut, Lambeth. I can't think what made me do it. I can't help it. I used that address as I thought it would be the best place for me to receive replies. I got the names and addresses from directories." Frequent mention has been made in THE LANCET of the danger arising from the unrestricted use of free libraries by all comers. Sims in the above statement said that he did not know what made him do it. It is quite obvious, however, that the newspapers, filled recently with accounts of a notorious trial, probably suggested or helped to inspire the crime, and that the books of reference which with the newspapers were placed at his disposal in the New Cut Free Library supplied the means of carrying it out. It is the begging letter writer, however, more frequently than the blackmailer who finds warmth, light, comfort, and all else that he wants to assist him free of charge at the free library.

Inaccurate Death Certification.

At a recent inquest upon the body of a newly born child at Fulham a serious error of judgment was shown to have been committed by Mr. H. A. Ehrlich, a medical practitioner who had been asked to give a certificate for burial. According to the explanation which he gave in the witness-box he at first certified the deceased child as stillborn in order to enable the parents to have the body buried as such. This, he admitted, was not correct, and afterwards, when the parents found that proof of the fact that the child had lived for three hours and then died would allow them to receive an allowance from a benefit club, the medical man gave a second certificate embodying the true facts. It is not surprising that in such circumstances an inquest followed and that the coroner admonished the medical man with regard to the unlawful and dangerous course which he had pursued. In order to conduce to accurate registration and to prevent possible concealment of crime, as well as for other reasons, the 18th section of the Act of 1874, which at present regulates the registration of births and deaths, orders that "a person shall not wilfully bury or procure to be buried the body of any deceased child as if it were stillborn," and then proceeds to say that the authorities controlling burial grounds shall not receive the body of a deceased child for burial as stillborn without certain prescribed evidence that still-birth has in fact taken place. Such evidence may consist of "a written certificate that such child was not born alive, signed by a registered medical practitioner, who was in attendance at the birth or has examined the body of such child." This was the certificate, presumably, which Mr. Ehrlich gave. In doing so he disregarded the importance of absolute truth and accuracy in such matters from a public point of view and the reliance placed by the Legislature upon the honour and accuracy of the "registered medical practitioner." It is also well to remember the concluding words of the section: "Any person who acts in contravention of this section shall be liable to a penalty not exceeding ten pounds."

The Beauty Specialist.

The action brought recently by a lady against a "beauty specialist" practising in Bond-street had as its result a verdict against the defendant for £500, with a statement by the jury that they considered her to have been guilty of fraud. The damages will hardly compensate the plaintiff for the disfigurement inflicted upon her by the defendant who, pretending to remove three small scars caused by small-pox, inflicted upon her a wound which but for the intervention of a medical man would have had even more serious results than in fact it did, and which, as it is, will leave a mark far more conspicuous than those which the "specialist" boasted herself able to nullify. Mrs. Heath, the plaintiff, may not perhaps be congratulated upon her wisdom in intrusting herself to an advertising quack, but she is at least to be commended for the courage with which she faced the ordeal of the witness-box, and the warning which she has thus publicly given to other women may save some from following her example. It is worth noting that the plaintiff had had her attention attracted to the defendant's professions of skill in the production of "beauty" by advertisements in newspapers devoted to supplying ladies with information as to the fashions and other subjects of special interest to them. The proprietors and editors of such periodicals, as anyone can see who chooses to read them, derive a large revenue from advertisements of "specialists" such as the defendant in the recent action, and they are not likely to consider the interests of their fair readers in preference to their own profits. Besides, however, inserting obvious and undisguised advertisements they allow and encourage the publication of articles laudatory of the quacks and their wares, in which the writers pretend to special knowledge of the efficacy of the methods which these important and lucrative advertisers employ and of the messes which they sell. The editor or proprietor of a newspaper is not necessarily responsible in all cases for the truthfulness of the statements made in the advertisements appearing in the portion of his paper devoted to them. It may, however, be suggested that his position may be different when he publishes an article in the body of his paper recommending in fulsome terms the advertisers' wares. He may not in so doing be guilty of conspiracy or of connivance with fraud, but is he not guilty of negligence if he has not ascertained or tried to ascertain whether what he publishes is true? The question may some day be answered by a person placed in the position in which Mrs. Heath found herself deciding that the damages which she hopes to obtain are more likely to be realised by suing a newspaper proprietor than by proceeding against a possibly impecunious "beauty specialist." The liability of the former may be moral rather than legal, but such a lawsuit as that suggested, if it were to reach the stage of being heard publicly, would be an awkward one to face.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8058 births and 4964 deaths were registered during the week ending Nov. 14th. The annual rate of mortality in these towns, which had been equal to 15·3 and 15·0 per 1000 in the two preceding weeks, rose to 15·9 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 14·2 per 1000, and in London the mean rate in the same period did not exceed 13·6. The lowest annual death-rates in these towns last week were 6·9 in Handsworth, 7·5 in Leyton, 8·0 in East Ham, and 8·4 in Hornsey; the rates in the other towns ranged upwards, however, to 25·6 in Wigan, 27·0 in Huddersfield, 27·2 in Middlesbrough, and 31·1 in Rochdale. In London the death-rate during the week was equal to 15·4 per 1000. The 4964 deaths from all causes in the 76 towns showed an increase of 281 upon the number returned in the previous week, and included 434 which elicited prolonged laughter and applause. The speaker further expressed the want of better housing accommodation for the poor in the locality, and pointed out that the want of a district nurse was very badly felt. Lady Aberdeen de- livered an interesting address on the aims and objects of the crusade, and stated that they were starting the van in that district as a sort of test before sending it to the West of Ireland for which it was intended.

Mater Misericordiæ Hospital.

On Nov. 5th the Annual Office and High Mass for the deceased benefactors of the Mater Misericordiæ Hospital were offered in the Pro-Cathedral, Marlborough-street. There was a very large attendance of clergy as well as a crowded lay congregation. The *clientèle* of the institution is necessarily a vast one, as it is by far the largest of the charitable institutions in this country for the professional relief of the sick and suffering poor. No question has ever been raised regarding the efficiency of the nursing attend- ance; the Sisters of Mercy are always on duty within its walls and had already introduced their own system (there and in St. Vincent's Hospital) years before the epoch-marking revolution of the training and employ- ment of lady nurses in our other institutions—in fact, at a period when a goodly proportion of our hospital, to say nothing of private, nursing was carried out in the true and original "Sairey Gamp" style. The daily average number of occupied beds in the Mater Misericordiæ Hospital is over 300; its annual attendance of intern patients is over 4000 and of extern attendances over 26,000. The devotion and skill of the nursing Sisters of Mercy have become a household word throughout the country and are fully recognised and appreciated by members of all the creeds and parties who are so prone to contradict one another's views on nearly all other public questions. And a specially significant fact in the history of this largest (and in many ways most representative) of our Irish hospitals is that it has never received any endowment and relies for its existence solely on the charitable devotion of a sympathetic people. And the requisite aid has never failed to be forthcoming.

The Dispensary Medical Officer not a Workman!

A very important decision, the first of its kind, has just been given in the Court of Appeal in regard to the validity of claim for injury made by a medical man (or his heirs, or executors, or representatives) under the Workmen's Compensation Act. Readers will remember that the widow of the late Mr. Denis Murphy, L.R.C.S.Irel., was awarded by the county court judge of Wexford a sum of £300 as compensation for the death of her husband which was due to the accidental collision of his dog-cart with a motor-car while he was engaged in the discharge of his duties as a dispensary medical officer. When the case was brought to the Court of Appeal by the guardians, who had been sued as his employers, the judges decided unanimously that the claim could not be upheld, inasmuch as the dispensary medical officer is *not* a working man. The decision, it need hardly be said, has produced a deep feeling of disappointment among the medical officers of the Poor-law service. The hope has been expressed that the Irish Medical Association, which had encouraged and supported the widow in the endeavour to uphold her claim, will be able to continue its advice and assistance till the case is brought before the House of Lords.

The Belfast Natural History and Philosophical Society.

On Nov. 10th, in the Belfast Museum, before a very large audience, Sir Otto Jaffe, LL.D., the retiring President, introduced in complimentary terms the incoming President, Sir John W. Byers, who, having first returned sincere thanks to the council of the Belfast Natural History and Philosophical Society, which for a period of 87 years had kept the lamp of learning burning in Belfast and had encouraged original research in various directions, delivered the inaugural address on the Folk-lore of the Ulster Child. Sir John Byers first described many curious customs associated with the birth of children, the supposed influence of the fairies, and matters considered lucky, or the reverse, in reference to infants. He then dealt very fully with the words and phrases applied in Ulster to children, relating many interesting customs, sayings, and old poems.

The Ulster Medical Society.

On Nov. 3rd Dr. T. S. Kirk, the new President, opened the present winter session by giving an address on Spinal Caries, dealing fully with its causation, diagnosis, and treatment. At the conclusion of the lecture he was awarded a warm vote of thanks.

The Belfast Hospital for Sick Children.

A sum of over £1000 has been paid to the treasurer of the Belfast Hospital for Sick Children to endow a bed in memory of the late Dr. S. Brice Smyth, the money having been contributed by his friends and patients.

Belfast Medical Students' Association.

At the inaugural meeting of this association, held in the Students' Union of Queen's College, Belfast, on Nov. 16th, Dr. Stewart, the incoming President, having delivered an address on Bygone Medical Superstitions, a lecture was given by Dr. E. F. Bashford, director of the Imperial Cancer Research laboratories, on the Experimental Investigation of Cancer. The practical result of these experiments so far was that they might be able at some future time to prevent the dissemination of the disease. On the motion of Professor W. St. C. Symmers, seconded by Mr. W. D. Thompson, B.A., a cordial vote of thanks was accorded to the lecturer.

Nov. 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the International Sanitary Bureau.

THE International Sanitary Bureau met on Nov. 4th at th Foreign Office under the presidency of M. Barrère, Frenc Ambassador to Italy. M. Pichon, Minister for Foreig Affairs, opened the proceedings in a speech in which he said that France was much flattered at having been chosen to be the country in which the meeting took place. The Italian delegate then replied in the name of his colleagues from the other Powers. After M. Pichon had left, M. Barrère rose to propose the selection of a president of the permanent committee of the Bureau. Despite the pressure which had been put upon him to accept the post himself he proposed the appointment of the Italian delegate, M. Santoliquido. This nomination was carried unanimously. The International Bureau owes its inception to a decision of the International Sanitary Conference held in Paris in 1903 and came into being a few months ago at an International Conference held at Rome. Here it was decided that the permanent seat of the Bureau should be at Paris.

The Open Sea Cure.

At a meeting of the Therapeutical Society held on Oct. 28th M. Laumonier showed that the therapeutic effect of sea air on the coast is quite different from that of the open sea—i.e., 20 or 30 miles out. On the coast the effect tends towards excitement and congestion and moreover is irregular in its action. Out at sea it is tonic and regulating (*équilibrante*) and in addition the patient gets quiet, a regular life, and a continuous bath of pure air. These advantages are not so patent on board great liners on account of the vibration and the smell from the engines, but on a sailing ship they are evident. M. Laumonier cited the case of an overgrown youth, aged 17 years, who was very neurasthenic. After a voyage in a sailing ship lasting 14 months he was quite well. He also stated that he knew a tuberculous patient, aged 36 years, who was obliged to cross twice a year from Europe to South America and whose health was always much better during the voyage. M. Laumonier concluded by pleading for the establishment of a "cure ship." She should be a sailing ship capable of making lengthy and slow cruises.

Fracture of the Neck of the Femur in the Aged.

Many surgeons have given up trying to get union in the case of an aged patient with a fracture of the neck of the femur, for such patients if kept lying down in bed are very liable to troublesome bedsores and to hypostatic pulmonary congestion, from which they generally die. Dr. Delbet has found a solution of this difficult problem and on Nov. 3rd he showed four patients at the Academy of Medicine whom he had treated with great success for fracture of the neck of the femur by a special method. Of the four patients one was 80 years of age, two others were between 60 and 70 years, and one was only 40 years. They could all walk and go up

Edward Middleton Newland, Lewis Albert Hodgkinson Lack, Kenneth William Mackenzie, Narindra Singh Sodhi, William Jackson Powell, and William Cowan Gray. The King has approved of the retirement of the following officers:—Lieutenant-Colonel Kavasji Cursetji Sanjana (dated Oct. 22nd, 1908); and Captain Donald Steel (dated Nov. 1st, 1908).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel Quinton Chalmers, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated Jan. 21st, 1908).

TERRITORIAL FORCE.

Infantry.

6th Battalion, Cheshire Regiment: The undermentioned officers, from the 4th Volunteer Battalion, The Cheshire Regiment, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Ralph Bennett Sidebottom and Surgeon-Captain Eugene Charles McCarthy. 4th (Denbighshire) Battalion, Royal Welsh Fusiliers: The undermentioned officers, from the 1st Volunteer Battalion, The Royal Welsh Fusiliers, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Richard Drinkwater and Surgeon-Lieutenant Jonas William Anderson. 4th Battalion, Welsh Regiment: The undermentioned officers, from the 1st (Pembrokeshire) Volunteer Battalion, The Welsh Regiment, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Major Evan Evans and Surgeon-Lieutenant William Reginald Eyton Williams. 5th Battalion, Welsh Regiment: The undermentioned officers, from the 2nd Volunteer Battalion, The Welsh Regiment, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Rhys David Morgan and Surgeon-Lieutenant Evan James Trevor Jones. 4th Battalion, the King's (Shropshire Light Infantry): The undermentioned officers, from the 1st Volunteer Battalion, The King's (Shropshire Light Infantry), are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Frederick Knollys Pigott and Surgeon-Lieutenant William Dyson (to be supernumerary). Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Charles Henry Gwynn, from the 2nd Volunteer Battalion, The King's (Shropshire Light Infantry), to be Surgeon-Lieutenant-Colonel with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). 4th Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment): The undermentioned officers, from the 1st Volunteer Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment), are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Captain Harry Legh de Legh and Surgeon-Lieutenant Clarence Barns Whitehead. 2nd Battalion, The Monmouthshire Regiment: The undermentioned officers, from the 3rd Volunteer Battalion, The South Wales Borderers, are appointed to the battalion, with rank and precedence as in the Volunteer Force (dated April 1st, 1908):—Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel James Rowlands Essex and Surgeon-Lieutenant Edward Meredith Griffith.

Royal Army Medical Corps.

Alexander Ogston is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the Highland Territorial Division (dated April 1st, 1908). Richard Caton is appointed to the Honorary Colonelcy of the Royal Army Medical Corps of the West Lancashire Territorial Division (dated April 1st, 1908).

For attachment to units.—Surgeon-Lieutenant-Colonel Frederick Henry Appleby, from the 4th (Nottinghamshire) Volunteer Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment), to be Lieutenant-Colonel (dated April 1st, 1908). Surgeon-Major Walter Moffett Hamilton, from the 3rd Volunteer Battalion, The Lancashire Fusiliers, to be Major, with precedence as in the Volunteer Force (dated April 1st, 1908). Surgeon-Captain William Hearfield Galloway, from the 2nd (Leeds) Yorkshire (West Riding) Royal Engineers (Volunteers), to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908). Captain William Young, to be Major (dated Sept. 25th, 1908). Lieutenant Robert Cross to be Captain (dated Sept. 25th, 1908). Surgeon-Lieutenant John Alexander Nixon from the 4th Battalion, The Gloucestershire Regiment, to be Lieutenant (dated April 1st, 1908).

3rd Highland Field Ambulance: The appointment to a Lieutenancy of Sidney Watson Smith bears date August 1st, 1908.

1st East Lancashire Field Ambulance: Captain Joseph F. Wright resigns his commission (dated August 29th, 1908).

3rd East Lancashire Field Ambulance: Captain Robert W. Beesley resigns his commission (dated August 20th, 1908).

5th London Field Ambulance: Lieutenant William Cameron Macaulay from the Royal Army Medical Corps, Territorial Force, to be Lieutenant (dated Oct. 7th, 1908).

3rd Welsh Field Ambulance: Surgeon-Major Arthur L. Jones from the 6th (Glamorgan) Battalion, Welsh Regiment, to be Lieutenant-Colonel (dated April 1st, 1908). Surgeon-Captain George A. Stephens from the 6th (Glamorgan) Battalion, Welsh Regiment, to be Captain (dated April 1st, 1908). Surgeon-Lieutenant Charles L. Isaac from the 6th (Glamorgan), Battalion, Welsh Regiment, to be Lieutenant (dated April 1st, 1908).

VOLUNTEER CORPS.

Rifle: 5th (Glasgow Highland) Volunteer Battalion, The Highland Light Infantry: Surgeon-Lieutenant-Colonel George Bell Todd resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908). 14th Middlesex (Inns of Court) Volunteer Rifle Corps: Surgeon-Captain Arthur M. Ware resigns his commission (dated March 31st, 1908). 2nd (Earl of Chester's) Volunteer Battalion, The Cheshire Regiment: The undermentioned officer resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 31st, 1908): Surgeon-Lieutenant-Colonel Alexander Hamilton. 1st (Brecknockshire) Volunteer Battalion, The South Wales Borderers: The undermentioned officer resigns his commission (dated April 1st, 1908):—Surgeon-Lieutenant William L. Pritchard.

At the Royal United Service Institution in Whitehall on Nov. 18th Colonel H. E. Rawson, C.B., R.E., read a paper entitled "A New Principle in Weather Forecasting and its Importance in Naval and Military Operations." Rear-Admiral A. M. Field, F.R.S., hydrographer of the navy, presided. We hope to publish the main points of the discourse next week.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Nov. 20th, 1830.

ST. THOMAS'S HOSPITAL.

CLINICAL LECTURE

DELIVERED BY

DR. ELLIOTSON,

Nov. 8, 1830.

VARIOUS CASES.

HOSPITAL REGULATION RESPECTING POST-MORTEM EXAMINATIONS.

DURING the last week, Gentlemen, that is, since the commencement of the present month, eight patients have been admitted, five of them men and three women. The cases among the women were, one of phthisis, one of epilepsy, and one of rheumatism. Amongst the men were, one case of paralysis of the wrists from lead, one of acute inflammatory dropsy, one of colic from lead, one of chronic diarrhœa, and one of inflammation of the glands at the angle of the jaw.

……

There has been one death. The patient was a woman, and the case one of apoplexy. There was, I am sorry to say, no inspection of the body. It is much to be regretted that in this hospital we cannot inspect patients who die without having first obtained permission from the friends.

Albert Apponyi, Minister of Public Instruction. The building is a good blend of hygienic and architectural features. It can accommodate altogether 160 insane patients. In a middle pavilion are the administrative offices and behind these are the laboratories and lecture halls. The patients, male and female, are accommodated in separate pavilions according as they are quiet or inclined to be violent, while a separate building is reserved for those suffering from infective diseases. The director of the new clinic, who has been appointed by the King, is Professor Ernö Moravesik, formerly professor of forensic psychiatry in the University. The admission of patients will begin with the new year.

The Position of Practice in Budapest.

Only a few weeks ago the Berlin practitioners complained of the excessive growth of the number of specialists in their city. To-day the Budapest practitioners also have to make the same moan. Every single branch of the medical science and art has representatives, many of whom are unable to earn their livelihood but still are able to spoil the practice of the general practitioners. An increase of polyclinics and other free institutions for medical attendance has followed and is also inimical to general practice. There is in Budapest a sick club with 120,000 members who have a right to free medical treatment. The State medical institutes keep up outdoor departments, where everybody can get medical advice without any regard to his financial circumstances, for the simple reason that in this way better statistics of work can be shown. The managers of these institutions like the great display of activity, though the quality of the work done is not what is shown but only the quantity. In order to alter somehow these conditions the general practitioners of Budapest propose to make an organised attempt to influence the leaders of the University so that the latter may insure free medical attention being given only to actual paupers. The specialist question will also be dealt with, it being sought that nobody shall be allowed to call himself a specialist unless he has spent five years in special study at a corresponding clinic. Such a radical enactment would much improve the material condition of the practitioners.

The New (Third) Medical Clinic.

In some five or six years the numbers of medical students in Budapest have trebled. While in the year 1900 the number of first year students amounted to 150, this year the number is 450. This great increase of students has necessitated the extension of the University Clinic. New hospitals have been built in quick succession, but still there were such crowds in the lecture halls that in the interest of those seeking instruction it became necessary to build extensively. The head of the clinic has already been appointed by the King of Hungary in the person of Professor Ernst Jendrassik who has gained his reputation as a neurologist, and his father, it may be recollected, was professor of physiology at the University of Budapest.

Nov. 14th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Sanitary Conference in United Provinces: General Conclusions.

THE following is a *précis* of the general conclusions of the United Provinces Sanitary Conference held at Naini Tal by order of the Lieutenant-Governor.

The conference considered at length the possibility of decreasing malaria, and notes on the subject by Colonel Murray, I.M.S., and Major J. Chaytor White, I.M.S., were considered. A special officer has been appointed to inquire into the prevalence of malaria in the United Provinces and his report will no doubt show what works should be undertaken in specially malarial tracts. Meanwhile, as a practical measure the conference recommends that a map of each district showing by the mortality returns the most malarial tracts should be prepared in the office of the Sanitary Commissioner. On the basis of this map district boards can carry out a detailed sanitary investigation into the condition of these tracts and systematic measures can then be taken for drainage, filling up insanitary pits and hollows, removal of noxious vegetation, and distribution of quinine. The conference has already proposed amendments to the Village Sanitation Act enabling the local authorities to prevent new excavations within or in the neighbourhood of inhabited sites and to fill up old excavations. It also suggests that the filling up or draining of existing railway burrow pits near inhabited sites is a question needing the consideration of Government, and that both railways and the Public Works Department should be prohibited from making such pits near inhabited sites in future. The distribution of quinine should be very considerably extended. The conference is informed that in an inquiry made in the Dinajpur district (in Bengal) three-fourths of the deaths from acute malaria were found to occur in children under ten years of age, and mostly in the autumn months. It therefore suggests that district boards should distribute quinine through village schoolmasters who are in a position to know when a child is absent from fever. Not only do children constitute the majority of victims, but it is in the blood of untreated children that the parasites thrive best and are conveyed by mosquitoes to adult persons. For the treatment of children some more palatable method of administering the drug than the bitter sulphate of quinine powders is essential. Distribution in the tabloid form has proved successful in the Duars tea gardens and might be tried in these provinces. The dose should not be less than ten grains; and although the sale of this amount at one pice (a farthing) involves a loss the expenditure would be well incurred. Another most important point which the conference wishes to emphasise is the extension of masonry surface drainage in towns large and small. The most dangerous varieties of anopheles breed in the earth-lined and grass grown roadside drains and are much more rarely found in tanks and small puddles. A most potent cause of malaria is thus situated at the doors of the inhabitants of the majority of Indian towns. Municipal boards should organise mosquito brigades to apply crude kerosine to collections of water in which the insects breed. The example of the Mizapur district board which is placing fish in large permanent tanks might be followed. A general thinning of trees and shrubs on scientific lines in some of the towns of this province is also essential and power should be given to municipal authorities to deal with trees and shrubs in private enclosures on the lines of Section 99 of the Cantonment Code, 1899, care being taken to obtain expert advice in the case of any general felling of trees. The question of restricting irrigation in the neighbourhood of towns and villages is of great importance. In a resolution passed in January, 1855, to give effect to the Canal Act of that day, the following limits were laid down:—

From military stations	5 miles.
From towns with over 10,000 population	1 mile.
" " 5,000 "	½ "
From large villages with over 1,000 population... ...	½ "
From villages with less than 1000 population	200 yards.

These provisions have not been enforced and would cause considerable hardship and loss of revenue if now insisted on. Canal irrigation has been restricted in the neighbourhood of towns in various instances—e.g., Barant, Shamli, Kosi, and Jansath. The conference accepts the general principle that where it is possible with due regard to agricultural interests it is desirable to exclude canal irrigation from certain areas round towns and villages. What this area should in each case be should be fixed by the sanitary authorities and the enforcement or non-enforcement of the exclusion should be carried out by the revenue authorities in consultation with the sanitation department. Rule 7 of the rules made under the Canal Act, 1873, should be communicated to municipal boards in canal districts and incorporated in the *Municipal Manual*. This rule provides that the divisional canal officer may, with the previous approval of the Commissioner, prohibit the use of canal water for the irrigation of any *kharif* crop, when the land to be irrigated is situated within one mile of the uttermost houses of any town if such irrigation be objected to by the municipal committee. A note furnished by Mr. Streatfield shows that practically the entire programme for drainage works in canal districts in connexion with canals has been completed, with the exception of a few works on the Eastern Jumna Canal. The conference suggests that the irrigation department should take up the question of drainage in other than canal districts, the staff if necessary being strengthened for the purpose. The special officer deput [illegible] uire is embalmed in a word in modern use. Artery has also been derived from ἀείρω (I raise) and from ἅλλομαι (I leap), but on the whole its derivation from Ἀήρ seems most likely to be correct. There is nothing novel, of course, in this supposition, but as far as I know no attempt has hitherto been made to reconcile the apparent discrepancy between the etymology and present meaning of the word asphyxia.

I am, Sir, yours faithfully,
LEONARD GUTHRIE.

Upper Berkeley-street, W., Nov. 16th, 1908.

THE CAUSE AND PREVENTION OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—I have been much interested in reading Dr. J. Sim Wallace's article on the above subject which appeared in your issue of Sept. 12th. Dr. Wallace and Dr. Campbell have rendered a useful service in bringing this subject prominently before the profession, and nothing but good can arise from following out the principles there set forth.

May I, however, be permitted to state that the germ of most of Dr. Wallace's writings appeared nearly 30 years ago in my father's work on dental surgery[1] (see pages 103, 104, 105, 106, 107), although this germ has not been allowed to develop in present day text-books on dental surgery. For this reason it is all the more gratifying to see that the subject of diet in relation to dental caries and the effect of the former on the hard and soft tissues of the jaws and their surrounding parts has now been placed on a firmer basis, and perhaps this time to take root. I am, Sir, yours faithfully,

London, Nov. 11th, 1908. F. COLEMAN.

THE ELECTROLYTIC ADMINISTRATION OF DRUGS.

To the Editor of THE LANCET.

SIR,—Your interesting annotation on the above subject in THE LANCET of Oct. 31st, p. 1314, is evidence of the recrudescence of interest in cataphoric medication. In your number for Oct. 25th, 1890, p. 869, i.e., just 18 years ago, you did me the honour to publish a short paper on "Cataphoric Medication and Cocaine as a Local Anæsthetic," and I then endeavoured to show that the method there described had already passed beyond the stage of experiment into that of routine practice, at any rate in my own hands. Subsequently (March 13th, 1891), at the Society of Arts, under the distinguished presidency of Mr. (now Sir) William H. Preece, F.R.S., I demonstrated *practically* some of the powers of the cataphoric method; and again in a paper on "Some Therapeutical Applications of Continuous Current" read at the opening sessional meeting of the Therapeutical Society in October, 1904, I referred to some portions of the work I had done in connexion with the cataphoric and other powers of continuous current. (I am inclosing herewith a marked copy of this paper.)

For some 20 years, therefore, as shown, I have used cataphoric medication in my everyday practice, and I am somewhat amused, though interested, to note that the subject is now treated as *new* by Leduc, Jones, and others, presumably on the assumption that no work on the subject has previously been done. May I here say that the new term "ionisation" is scarcely comprehensive, and there are weighty objections to its use—except in so far as it implies a *part* of a process! In connexion with recent papers I note that the writers have not yet grasped the necessity for paying regard to antecedent *voltage* (as demonstrated by the late Mr. Lant Carpenter, Dr. W. H. Stone, and others), or to relative area of contact of the respective electrodes.[2] Too much stress has been laid upon "*ionisation*," which, though an essential part of cataphoric medication, is, after all, *only a part* and does not include the whole of the processes concerned.[3]

Verily, there is nothing new under the sun! Long before I attempted to employ medication by cataphoresis the late Sir Benjamin Ward Richardson and others in Germany and America had already carried their investigations into an advanced experimental stage.

With regrets for trespassing so far on your valuable space and my best thanks in anticipation,

I am, Sir, yours faithfully,
ARTHUR HARRIES.

St. James's-square, Pall Mall, S.W., Nov. 7th, 1908.

⁂ We remember our correspondent's interesting paper. We do not see that our annotation implied that either Leduc or Jones considers that cataphoresis is "new." Dr. Lewis Jones was using cataphoric medication by cocaine in 1899 at St. Bartholomew's Hospital. The originator of electrical medication was Fabre Palaprat, who wrote in 1833 on the introduction of iodine into the tissues by means of currents. In a bibliography of the subject given in 1900 by Professor Leduc, Dr. Harries's paper is mentioned and occupies the twenty-fourth place in chronological order.—ED. L.

A SERUM TREATMENT FOR CARCINOMA IN MICE.

To the Editor of THE LANCET.

SIR,—My attention has been called to Mr. C. E. Walker's letter in THE LANCET of Nov. 14th. I, too, would have hoped —had I given the matter a thought—that the discussion should have begun and ended with the meeting of the Liverpool Medical Institution (at which the paper in question was read by him) and the subsequent reports in those journals which thought the matter of sufficient importance to publish. It is contrary to the usual procedure to carry on a discussion in the medical press after a meeting unless material facts or arguments are wrongfully supplemented later in the report of that meeting. This did not occur.

I must deny any intention in my remarks other than that of impartial criticism of an important subject in which I am, as most of the profession are, much interested. Further, I have always held that to anyone who has a good case, knows his subject, and has the opportunity to reply, criticism should be welcome, in that it helps him to make good the weak points in that case. Mr. Walker failed in his reply to make a single point. He has since, I take it, worked the subject up; hence his letter.

Since he has alluded to the courtesy of the Medical Institution, which is justly proverbial, I presume he thinks my remarks were discourteous. I hasten to disclaim any intention of discourtesy at all. I would remind Mr. Walker that since *he asked to be invited* to read his paper he could not consider himself in the light of a distinguished guest. Had such been his position my remarks would have been in bad taste and uncalled for. While we are on this matter I must say also that in any circumstances I think the position of the Liverpool Medical Institution is such that he was ill-advised to read before it a paper which he had published in THE LANCET only a few weeks previously—it was hardly a compliment to the institution. I feel it necessary to say this much, and also to deny the insinuation that I abused the hospitality of the Cancer Laboratory. I was never Mr. Walker's guest, nor did he ever give me any mice. I grafted myself what mice I had from one kindly given to me by the director of the laboratory. These are personal details I am sorry Mr. Walker has dragged in. I have no wish in regard to the work of that laboratory but that some good should come out of it, and that the indefatigable energy of the workers there should meet with some reward. If he considers my remarks a "reflection" on the laboratory I can only reply that my intention was to save it from what happened recently on the publication of work done there in connexion with liquid air—work which was criticised in a similar manner by Dr. E. F. Bashford.[1]

Mainly my complaint was, then, that no reference at all was made by Mr. Walker to the work of others on similar lines (with the exception of a small experiment of Grünbaum done in the same laboratory). I carefully mentioned in my remarks that there *was* a difference in technique in some of the work but that there was no *essential* difference. The few remarks made in reply showed that with the exception of some of Borrel's work he was unfamiliar with, or ignorant

After holding resident appointments at St. Luke's Hospital, London, the Belgrave Hospital for Children, London, and the Whitehaven and West Cumberland Infirmary, Mr. Henley was in 1882 appointed as assistant medical officer at the Gloucestershire County Asylum at Wotton. He remained at Wotton for two years and was then transferred to the new asylum at Covey Hill. In October, 1906, he was appointed medical superintendent of the Gloucestershire County Asylums, succeeding the late Mr. F. H. Craddock. Mr. Henley was extremely popular in Gloucester and the district; he was a most efficient medical superintendent of the county asylums and much regret is felt at his early death.

THE MEDICAL INSPECTION OF CHILDREN IN LONDON.

THE London County Council this week has approved of a tentative scheme for the inspection of school children in London as required by Section 13 of the Education (Administrative Provisions) Act. The routine of inspection is to be undertaken by means of a temporary staff who will give a part of their time—averaging three half-days a week—to the work, and it has been attempted so to arrange the scheme that any practitioner who feels drawn to this branch of practice will have a reasonable chance of obtaining the knowledge and experience to be derived from school work. Medical inspection without medical treatment of any kind is the only work to be undertaken by this staff.

The scheme provides for the division of the metropolis into 16 districts which generally coincide with the school attendance areas, though these in some instances are subdivided. Each of these districts will be allotted to a school medical officer, the present assistant medical officers of health holding the posts for the present. There will be assistant school medical officers appointed in each district, and these posts are now being advertised. At the end of three years it is designed that the whole staff will number 16 school medical officers with 56 assistants, and all who enter the service will do so in the first instance as assistants with annual appointments. This means that after the election to the posts now advertised there will be an annual election of 24 assistants to commence work on Sept. 1st of each year, the salary, including travelling expenses, being £120 per annum. General practitioners in the various localities will be eligible for the appointment, but it is expected that a certain number of men not in general practice will always be appointed.

School medical officers are to be appointed from among the assistants after at least one year's service at a salary, including travelling expenses, of £150. A rota will be established in the following manner. None of the officers doing this routine work will be eligible for reappointment after the third year from entering the service. Most men will therefore retire after three years' service as assistants, and eight in each year after three years' service partly as school medical officer and partly, for a year at least, as assistant. The school medical officers are to be given considerable responsibility for the routine work in their districts and may also in accordance with instructions carry out special inquiries or investigations in the course of that work. Other inquiries and special examinations or urgent matters will continue to be dealt with as hitherto by the chief education medical officer and the assistant medical officers of the permanent staff.

The scheme is a large one and whether it be acceptable to the medical profession on all grounds or no, it must receive the credit due to thoroughness. The conditions of service being elastic, all members of the medical profession are eligible and under the rota system the benefits of experience are open to the maximum number of the profession. Future appointments can be created without dislocation of existing arrangements by simply increasing the number of assistants to be elected annually. It seems probable that promotions from among the assistants will not generally be made in favour of the general practitioner, the choice of the school medical officers from among those not in general practice being defended on the ground of avoiding invidiousness in elections; but this, the remuneration of the assistants, and several other points will require future consideration.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians on Oct. 29th, and at an ordinary meeting of the Council of the Royal College of Surgeons of England on Nov. 12th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred by both Colleges on the following gentlemen who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board:—

James Wilmot Adams, B.A. Cantab., Cambridge University and St Bartholomew's Hospital; Frank Robert Lowth Atkins, Guy's Hospital; Martyn Wilfred Baker, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Malcolm Edward Ball, Guy's Hospital; Henry Lewis Barker, St. Mary's Hospital; Ernest Urquhart Bartholomew, L.M.S.S.A., Charing Cross Hospital; Charles Botterill Baxter, M.B., Ch.B. Edin., Edinburgh University and London Hospital; Arthur Cecil Barker Biggs, University College Hospital; Charles Newton Binney, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Clement Henry Burton Bradley, M.B., Ch.M. Sydney, Sydney University; Lancelot Stephen Topham Burrell, M.A. Cantab., Cambridge University and St. Thomas's Hospital; *John Joseph Cameron, M.D. Toronto, Toronto University and London Hospital; Arthur Laurence Candler, St. Bartholomew's Hospital; Alfred Edward Arthur Carver, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Bernard Arthur Cheadle, St. Thomas's Hospital; Bertie Isaac Cohen, St. George's Hospital; John Hutchinson Crofton, B.A. Cantab.,

the way in promoting an Act for the notification of births of infants. Belfast can go for special Acts for its tramways, for its city hall, and for other objects, but alas, the illness and the deaths of its citizens from preventable diseases are apparently of much less moment. With reference to the shell-fish hypothesis as accounting for the existence of typhoid fever in Belfast, the committee in its report points out that in the year 1907 there were 356 notifications of enteric fever and of these only 14 were attributable by the patients or their friends to the eating of shell-fish; and it gives in the appendix articles by Professor J. Lorrain Smith and Professor A. E. Letts dealing with the question of the causation of enteric fever in Belfast. The matter may be left between the public health committee and the Belfast water commissioners, as the committee of the corporation is anxious to have a conference with the water commissioners in reference to another suggestion of the Health Commission that "the water-supply of Belfast should be in the hands of the corporation."

As to the conclusions and numerous suggestions made by the Health Commission in regard to the organisation of the public health department, they are dealt with in rather an extraordinary way by the combined committee of the corporation. To give some examples: The Commission says, "The hospital accommodation provided by the corporation for infectious diseases is inadequate and should be increased, and the guardians relieved of all responsibility for the treatment of these diseases."

In 1906 the Purdysburn fever hospital with 168 beds (there is an adjacent temporary hospital for small-pox with 74 beds) was opened, and, save the small-pox one, it was the first fever hospital owned by the corporation. There are 200 beds for the treatment of infectious diseases provided in the union fever hospital by the board of guardians. The committee says: "Hospital accommodation at present is more than ample. The union fever hospital has never in practice been regarded as a pauper institution." Now both these statements are inaccurate. The Health Commission reports (p 74) that "even with the present use of beds in the union hospital the total provision of hospital accommodation is inadequate" and "partly as a result of the inadequacy of hospital accommodation a large proportion of the cases of infectious disease in Belfast has been treated at home," and of those left at home, the medical officer of health said at the Commission fully one-half were inadequately isolated. Further, the Commission recommends that not only should the corporation frankly accept sole responsibility for dealing with infectious disease within the city and make adequate provision for such cases as require removal to hospital. The union fever hospital, though an admirable place, has always been regarded as a pauper institution, as any medical man could explain as he finds the difficulty in getting patients to enter it. In his annual report for 1907 the medical officer of health states in reference to the fever hospital at the union workhouse (p. 40) "that a large number of the people was prejudiced against going there." Suppose, as occurred before, there were 400 typhoid cases, What would be the use of a hospital with 163 beds for all types of fevers except small-pox? To many of the other suggestions of the Health Commission the committee replies: "This is being done as far as practicable"; "The corporation has been working with this object for some years and has partly succeeded"; "Your committee concur in this opinion and steps have been, and are being, taken to give effect to it"; "This is also in hands"; "This is under consideration," &c. In other words, to all the admirable recommendations of the Health Commission, given with the object of trying to instruct the corporation in the simplest principles of sanitary science and public health, no proper or sufficient reply is given beyond they are "in hands," "under consideration," which really means that unless the Local Government Board or the public insist, little or nothing may be done to carry these suggestions into effect. Finally, with reference to house cleansing the committee says:—

> The substitution of water-closets for privies is recommended by the Commission as a great sanitary reform. They criticise severely the unpaved back passages, the defective ashpits, and insufficient cleanings, but they seem not to have realised the phenomenal rate at which the city has developed and of the difficulties of keeping pace with that development without overloading the city with taxation. All the up-to-date sanitary luxuries in the way of hospitals, elaborate systems of sanitary administration, and such like, would have been provided long ago if the people could have borne the burden; but while Belfast is a [illegible]ulous place, and its death-rate may compare favourably [illegible] English and Scotch cities, yet its municipal financial resources or the private resources of its citizens are far behind those of the cities on the other side of the channel.

There are several inaccuracies in this statement. 1. The growth of Belfast has never been so "phenomenal" as to prevent the adoption of proper sanitary arrangements had the various authorities done their duty, and the people would not have objected, as had various necessary public health measures been adopted step by step taxation would not have been great. Why was the Notification of Infectious Diseases Act never adopted until 1897, and why was a municipal fever hospital not opened until November, 1906? And why has the corporation not had a bed for a consumptive until October, 1908? 2. The death-rate of Belfast does not compare favourably with that of English and Scotch cities. Even adopting the hypothetical population assigned to it by the Health Commission (an estimate denied by the Irish Registrar-General who is the recognised Irish Crown authority on statistics), the general death-rate of Belfast is about the same as that of Manchester, better than that of Liverpool, and not so good as the other cities; that is only one large city in England or Scotland is worse; while from enteric fever and phthisis the death-rate of Belfast is not only excessive but far above that of any large city in England and Scotland; indeed, as the Health Commission puts it, "the mean annual mortality from enteric fever has been so exceptional in Belfast for the last 25 years that it appears to have no parallel in any other city or large town in the United Kingdom." 3. The municipal financial resources and the private resources of its citizens may be behind (*not far* behind as the committee states) those of the cities on the other side of the Channel but the recent erection of a new palatial city hall at a cost of between £300,000 and £400,000, the large expenditure on the asylum, and the publication from time to time of the wills of deceased Belfast citizens do not support the view that the people of the city could not and would not cheerfully have borne a taxation which would have had the effect of diminishing sickness and of preventing the deaths of many people from diseases now regarded as largely preventable. No person who has lived all his life in Belfast, and who has seen how neglected the science of public health has been from a corporation point of view, could accept any such excuse.

If the Belfast corporation, under wise and proper guidance, had exhibited any foresight and common sense, such as was displayed in other English and Scotch large cities, on behalf of the public health, and had it introduced one after another the ordinary preventive measures, and had it acted on the advice of its own committee (the "Harrison"), not only would the death-rate of the city have fallen as it has done in these other cities but any necessary taxation to carry out these schemes would not have been felt. It did not do so and as a consequence it finds itself forced now to face a number of problems (of which the greatest is the pollution of the shores of Belfast Lough by the sewage of the city) which will certainly, owing to its carelessness and neglect, be a much heavier financial burden. There is no help for it, for it is as true in municipal administration as in other affairs of life: "As you sow, so shall you reap"; and after all there is, if the corporation does not decide to solve these health problems adequately, only one alternative—more preventable deaths and more illness. It may readily be granted that recently there has been an improvement in dealing with some public health questions, and there is truth in what one of the city councillors said in the discussion on Oct. 22nd (as reported in a Belfast daily paper):—

> There were human beings living within half a mile of the city hall under conditions such as no self-respecting citizen would allow his dogs or animals to be congregated in. It was a credit to the health department that since the appearance of the Health Commission more real public health work had been accomplished by that department during the past two years than in any 25 years previously. He held that the public health department was never awake to its duty until the vision of the Commission appeared on the horizon, and every right-thinking citizen felt gratified at the result. If the work could be undertaken in a practical way in the beginning of 1907 what was to prevent it being taken in hand ten years ago? But for the action of certain public-spirited citizens that council would still be wrangling over the same questions as agitated the corporation ten years ago

---

A DORSET CENTENARIAN.—Mrs. Mansfield of Zeals, near Shaftesbury, Dorset, has just celebrated the hundredth anniversary of her birthday. She is a near relative of the late Queen Victoria's nurse, Lilley. The King sent a congratulatory message to Mrs. Mansfield.

C. J. Thomas and Dr. A. H. Hogarth of the London County Council Education Department, Dr. H. Meredith Richards, Mr. P. Macleod Yearsley, Mr. C. Edward Wallis, and others. The subjects will comprise general medical inspection of school children, special medical inspection, eyes, ears, teeth, infectious diseases, defective children, school and home, office routine, and the preparation of reports. The course is open to all medical graduates, and those desirous of attending should make early application to Mr. W. A. Lawton at the offices of the Society of Medical Officers of Health, 1, Upper Montague-street, Russell-square, London, W.C., as accommodation is only available for a limited number.

A CASE OF KALA-AZAR IN VIENNA.—Much interest has been shown in a case of kala-azar now under treatment in the Vienna Clinic for Children's Diseases. It is the first case observed there. The patient, a Russian child, nine years of age, presented the following symptoms: extreme emaciation, swelling of the abdomen, and increase of the size of the liver, spleen, and other glands. An exploratory puncture of the spleen was made at the clinic with the idea of searching for the micro-organism of kala-azar, and the diagnosis was confirmed by the cultures obtained. The interest of the case lies also in the fact that in Odessa, whence the child came, several cases have occurred quite recently according to the mother of the boy, whilst formerly kala-azar was unknown there.

WIMBLEDON AND DISTRICT MEDICAL SOCIETY.—The session 1908–09 of this society began last Friday, Nov. 13th, by the delivery of an address by Sir William H. Bennett upon Swellings of the Knee-joint not due to Injury. The following is the list of papers set down for future reading and discussion: On Friday, Dec. 11th, Mr. J. Howell Evans on Swellings and Tumours of the Breast, illustrated with lantern slides and specimens; on Friday, Feb. 12th, 1909, Dr. C. O. Hawthorne on Some Clinical Aspects of Functional Paralyses; on Friday, March 12th, Dr. Edmund Cautley on the Use and Abuse of Proprietary Foods in Infant Feeding; and on Friday, April 18th, Dr. James Galloway on Some of the Commoner Affections of the Skin: their Exact Diagnosis and Treatment.

THE BRIGHTON AND HOVE WOMEN'S HEALTH SOCIETY.—This society is ceasing to exist neither from want of funds nor from any lack of interest on the part of those who have been carrying on the work unostentatiously for the past 13 years. The society is winding itself up because, owing largely to its success, public measures will now replace private effort. The town of Hove has appointed a health visitor and Brighton will follow suit in the near future, so that the work of the society will be carried on by the municipal authorities and there must be no interference with the work of these officers by volunteers not answerable to the ratepayers. A great deal has been done by the society since its inception in 1895. Dr. A. Newsholme, the principal medical officer of the Local Government Board, was the medical officer of health of Brighton at the time, and it was in consequence of one of his reports respecting infantile mortality that a few ladies banded themselves together and instituted a society which they very appropriately named the Brighton and Hove Women's Health Society. Their chief aim has been throughout to combat excessive infantile mortality and their work has been the instruction of classes of women in the elementary laws of health and the sound hygienic care of their children. Young girls have also been taught how to aid their parents both in the home and without, and how to take charge of their younger brothers and sisters. Then, too, where the need has been found the society has lent fire-guards for the homes of poor people, and in other ways has lent timely assistance to many a poor home. A local correspondent writes:—"While the steps taken by the municipal authorities are welcomed the loss of such an organisation is to be regretted. The balance of the funds in hand is to be utilised for the benefit of both boroughs under the rules of the society, and its officers will remain existent until the money is exhausted. The extinction of the society and the municipal authorities stepping in point to the advance of public opinion on such important questions as the rearing of children and hygiene in the home." This is undoubtedly true, but it is equally true that voluntary workers may prove more effective in educating women in the laws of health than the municipal health visitors, and it is hard to see why Brighton and Hove cannot arrange to make use of the existing society, the efforts of which might be concurrent with those of the municipalities.

DR. E. OTT, well known to many English members of the medical profession through his practice at Marienbad, has started a winter practice at Meran, Tyrol.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the distribution of certificates and badges to members of the Great Western employees' branch of the St. John Ambulance Association at Chippenham held on Nov. 8th under the presidency of the mayor, Mr. William Thomas Briscoe, M.D., M.Ch. Dub., was presented with a silver cake-basket in appreciation of his services as honorary lecturer.

ROYAL INSTITUTION.—The eighty-third Christmas course of juvenile lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Professor William Stirling, M.D., LL.D., D.Sc., his subject being "The Wheel of Life." The course, which is to be fully illustrated, will commence on Tuesday, Dec. 29th, at 3 o'clock, and will be continued on Dec. 31st, 1908, and Jan. 2nd, 5th, 7th, and 9th, 1909.

THE annual dinner of the Royal Free Hospital and School of Medicine for Women will be held at the Hotel Cecil, Strand, W.C., on Wednesday, Dec. 9th, at 6.45 for 7.15 P.M. Miss L. B. Aldrich-Blake, M.D., M.S., will take the chair. There will be a musical conversazione after dinner. Applications for dinner tickets should be sent to the honorary secretaries, Mrs. Florence E. Willey and Mr. George P. Mudge, not later than Saturday, Nov. 28th.

THE GLASGOW UNIVERSITY CLUB, LONDON.—The autumn dinner of the Glasgow University Club, London, will be held at the Trocadéro on Friday, Nov. 27th, at 7.30 P.M., when Professor A. Barr, D.Sc., will take the chair. Dr. C. O. Hawthorne, who has recently resigned the honorary secretaryship of the club, will be the special guest of the club at this dinner. Members desiring to attend should send their names and those of their guests to Mr. W. Craig Henderson, 2, Paper-buildings, Temple, E.C., not later than Tuesday, Nov. 24th.

THE MIDDLESEX HOSPITAL SMOKING CONCERT.—Sir A. Conan Doyle will preside at the eighteenth annual smoking concert arranged by the students of the Middlesex Hospital at the Queen's Hall, on Tuesday, Nov. 24th. The proceeds are given to the Middlesex Hospital cancer ward, so that those who attend the concert (to which ladies are cordially invited) assist a most deserving and necessary charity. Many of the leading artists of the theatrical and music hall stages (by permission of their respective managers) have consented to appear. Tickets may be obtained from the honorary secretaries of the concert at the hospital or at the Queen's Hall.

DONATIONS AND BEQUESTS.—At a recent meeting of the board of managers of the Edinburgh Royal Infirmary it was intimated that the late Mr. Peter K. Easson of Kinnoull Cottage, Perth, had bequeathed a one-third share (estimated to amount to about £5300) of his estate to the infirmary; it is to be known as the "Easson Brothers Bequest."—The late Mr. H. J. Randall of Bridgend (Glamorganshire) has bequeathed £6000 to the Bridgend Cottage Hospital.—In memory of the late Mr. Alfred Boyd of Sandon, Essex, an ex-member of the Canadian Parliament, his widow has given £1000 to St. Bartholomew's Hospital to provide scientific instruments.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 12th, Dr. F. H. Champneys being in the chair. A letter from the Clerk of the Privy Council as to the procedure to be adopted in prosecutions under Section 12 of the Midwives Act, 1902, was considered. This section is as follows: "Any person wilfully making or causing to be made any falsification in any matter relating to the Roll of Midwives shall be guilty of a misdemeanour, and shall be liable to be imprisoned with or without hard labour for any term not exceeding twelve months." The Clerk of the Privy Council in his letter said that in reference to the particulars of the case in which a medical practitioner was alleged to have issued a false certificate to a woman, he was directed to state for the

Westphalia." By this time, however, it was difficult for speakers to command the attention of the company, and therefore the banquet was soon brought to a close amidst much enthusiasm and many felicitations.

On Friday afternoon (Oct. 2nd) nearly all the members of the Congress went to the White House. Here a *queue* stretched from the street through the gardens and along the corridors of the Presidential residence. Most persons had to wait an hour and some longer before it was their turn to be ushered into the presence of the President and then, of course, there was no time but for the exchange of the briefest salutations. On the other hand, everybody who chose to wait received the traditional presidential shake of the hand and further was introduced to Mrs. Roosevelt. This ceremony gave an opportunity of seeing over a part of the more than modest residence of the President of the United States. It is certainly only just to call it the White House, for it is simply a house; there is nothing palatial about it.

On the same evening, and in the same great hall where the Secretary of State had given his banquet, there was "a smoker," as it was called. This was a tremendous gathering at which several thousand persons assembled, smoked, drank beer and punch, and ate refreshments dispensed from a large buffet. It was a good opportunity for conversation and for meeting old friends. This entertainment was offered to the Congress by the District of Columbia committee. On the Saturday afternoon the ladies' committee of the District of Columbia chartered a steamer and took a number of members on an excursion down the Potomac river. Altogether, therefore, the week at Washington was not absorbed entirely by study and discussion, for our American friends were not able to forbear from offering us the various kinds of hospitality which I have thus briefly described.

The Congress concluded on Oct. 3rd by a general session of valedictory addresses by the representatives of States and nations. Towards its conclusion President Roosevelt unexpectedly appeared on the platform and delivered an address in which he emphasised the need for the coöperation of practical men with men of science. The following week was devoted to the exhibits and a series of popular lectures and special meetings which attracted great attention in Washington. The need for a campaign of hygiene has been in part felt, and only this summer Dr. Woodward, medical officer of health, inaugurated a crusade against unclean lunch-rooms, but the doctrine of the open window, which has contributed so largely to the lowering of the death-rate in England during the last five years, has not in this part of the world yet received the acceptance which it merits. A series of lectures was then taking place in the public schools, and one day during the week was devoted to demonstrating the exhibits to the high school children of the city, who were conducted in sections and had the simple points explained to each one. The different Government departments were each allotted a special time for visiting the exposition; and even some of the large storekeepers permitted their employees to leave work in order to learn lessons conveyed by it. The ventilation both in the Government departments and in the stores is particularly defective in Washington. It is to be hoped that the lessons of the Congress on Tuberculosis will lead to more activity in a judicious provision of means of ventilation, at least during the winter. The Congress would indeed be a failure if in the very city where it was held some such practical benefit is not its outcome.

WORK OF THE SECTIONS.

THURSDAY, OCT. 1ST.

Immunity.

The production of immunity was discussed on Thursday morning, and some promising investigations were reported. The discussion began by a review of previous work by Dr. BALDWIN (Saranac). He considered that this work held out no prospect of an immunity of long duration, as even the dosage of living bacteria only protected for a time. He believed that a method of measurement must be devised. The problem was, firstly, one of creating tolerance for the bacillary poisons or products when undergoing autolysis and their assimilation by the tissues. Bartel's and Opie's studies on the influence of the white cells upon bacilli were very encouraging, and the present studies on anaphylaxis might add needed light. The present trend of investigation was to devise a method to meet the problem, for which solutions had been suggested, such as spacing the interval between inoculations (Pearson and Gilliland), feeding with the vaccine (Calmette and Guérin), inserting encapsulated bacilli (Heymanns), not to mention Pasteur's classical method of attenuation of virulence by passage through other animals. [In this connexion it was unfortunate that the Belgian exhibit containing Heymanns's preparations was detained in New York for three weeks, and that the congressists were thus deprived of the remarkable specimens devised for the illustration of his method.]

Professor CALMETTE (Lille) recalled his famous experiments at the Lille Pasteur Institute but believed that the method there investigated was less desirable than the use of tuberculin, which was equally efficient and did not subject the subjects to the disadvantage of being the carriers of bacilli, which after six or eight months of quiescence were certain to give rise to active tuberculosis. In some of the cattle which were merely fed with tubercle bacilli, however, the glandular infection had disappeared after three or four months, while their immunity lasted over a year. This immunity, however, merely consisted of a temporary failure to react to an infection.

Dr. BARTEL (Vienna) described his method of attenuating bacilli by the action of lymphocytes.

Dr. COURMONT and Dr. LESIEUR (Lyons), from experimenting upon guinea-pigs with very virulent cultures of bovine bacilli, formed the opinion that a tuberculous lesion in process of evolution prevented a second infection.

Dr. WEBB and Dr. WILLIAMS (Colorado) and Dr. BARBER (Kansas) described their methods of producing immunity by inoculation of an increasing number of bacteria, beginning with a single organism. They indicated the analogy with vaccination against small-pox. By this method they had induced complete immunity in guinea-pigs and were now experimenting with rabbits. They had succeeded in introducing 10,000 organisms at once by subcutaneous inoculation without producing tuberculosis.

Dr. GABRILOWITSCH (Halila, Finland) using "tuberculinum purum," reported that great improvement occurred in 25 cases thus treated. In 59 per cent. of these the bacilli disappeared from the sputum, while they were much diminished in 21 per cent. The catarrhal symptoms in the lungs ceased in 75 per cent. and diminished in 25 per cent. The temperature became normal in 21 per cent. during the treatment and in 62 per cent. when the treatment was complete. The course lasted from 40 to 60 days and the dose was increased from 0·01 milligramme to 100–200 milligrammes, requiring about 20 injections. In 96 per cent. of the cases the weight increased from 1 to 6 kilogrammes. Tuberculinum *purum* induced von Pirquet's reaction and had the advantage of producing no annoying reactions.

Professor CALMETTE, after reviewing the modified tuberculins of Klebs, Buchner, von Behring, Béraneck, and others and the later attempts of Denys, Maragliano, and von Ruk, described his preparation known as Tuberculin CL. He claimed that 50 centigrammes might be injected at once into the jugular vein of an ox without any elevation of temperature. This was due to the absence from his preparation of the albumoses, peptones, glycerides, &c., which so often vitiated the test when other tuberculins were employed. His preparation, however, was so active that after a third injection, given at intervals of from 8 to 10 days, there was a severe reaction of 1·8–2·5, with elevation of temperature, just as if the animal were tuberculous. The animal, moreover, acquired a high resistance to tuberculous infection; e.g., a dose sufficient in control animals to produce miliary tuberculosis in six weeks, in this immunised animal will only cause a tuberculosis of slow onset. This substance was prepared by centrifugalising "entire" cultures of bovine bacilli *in vacuo* at a low temperature. The bodies of the microbes were removed by filtration and the filtrate was then cleared from precipitants and salts by the use of alcohol and ether and, finally, by re-solution in water and dialysis, the colloids which remained being again precipitated with alcohol and ether and dried. In this process no heat that could injure the active principle was employed. Its activity was estimated by direct inoculation into the brain of a healthy guinea-pig, as suggested by von Lingelsheim. In this manner he found 0·0008 milligramme to be fatal, whereas it required nearly ten times as of specialists in these matters. There are four keys to it, which are held by the inspectors of police in the Lords and Commons, the Sergeant-at-Arms, and a representative of the Office of Works. I have no doubt that if and when the necessity should arise Members will receive in the future, as they have done in the past, the immediate and careful attention of their medical colleagues in this House.

TUESDAY, NOV. 17TH.

The Tuberculosis Prevention (Ireland) Bill.

Captain CRAIG asked the Prime Minister whether it was proposed by the Government to extend the scope of the Tuberculosis Prevention (Ireland) Bill to England and Scotland; and, if not, whether steps would be taken to prevent poor persons suffering from the disease in England and Scotland being sent to Ireland to be a burden on the rates.—Mr. ASQUITH replied: I am not in a position to make any statement as to the extension of the scope of this Bill to England and Scotland. The honourable Member's concluding inquiry opens up a large question with regard to the law of settlement which at present applies to England and Scotland but not to Ireland. My right honourable friend the Chief Secretary has, I am informed, expressed the intention of considering that question in connexion with contemplated legislation for the reform of the Poor-laws next year.

BOOKS, ETC., RECEIVED.

DAVIES, JOHN DAVID [illegible] Medical Officer by [illegible] Board of Guardians.

DEAN, GEORGE, M.B., C.M. Aberd., has been appointed to the Chair of Pathology in the University of Aberdeen.

DOUBLEDAY, [illegible] Farringdo[illegible] en appointed Dental Surgeon [illegible] Lying-in Charity.

GARDINER, [illegible] sg., D.P.H. Lond., has be[illegible] appointed [illegible] Surgeon to the Camborne (Cornwall) D[illegible] pensary.

GOULDEN, HERBERT EDWARD, L.R.C.P. Lond., M.R.C.S., D.P.H. Cantl [illegible] spector of Schools by the Dev[illegible]

LAN[illegible], M.R.C.P. Lond., has been ap[illegible] Mary's Hospital, London, W.

MAC[illegible] Ch. Oxon., has been appointe[illegible] Hospital for Consumption an[illegible]

PITT, CHARLES WIGHTWICK, [illegible] Medical Officer of Health o[illegible]

ROBERTS, G. A., F.R.C.S. Eng. [illegible] to the Royal Albert Hospital, Devonport.

SHARPE, F. A., M.B., B.S. Lond., D.P.H., has been appointed Assistant Medical O[illegible] unty Borough of Derby.

[illegible] rd., has been appointed District [illegible] t) Board of Guardians [illegible] has been appointed Surgeon to [illegible] Hospital.

THOMAS, JOSIAH TELFER, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Camborne (Cornwall) Dispensary.

TOSSWILL, LEONARD ROBERT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Inspector of Schools by the Devon Education Committee.

WOODROFFE, H. D., M.B., B.Ch., B.A.O., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

WYLIE, ANDREW, M.D., C.M. Glasg., has been appointed Surgeon to the Central London Throat and Ear Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon and Registrar. Salary £100 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing.

BARNSTAPLE, NORTH DEVON INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham road, S.W.—Assistant Surgeon.

BLACKBURN A[illegible] INFIRMARY.—Junior House Surgeon. [illegible] with board, washing, &c.

CARDIFF CITY MENTAL HOSPITAL, Whitchurch.—Junior Assistant Medical Officer, unmarried. Salary £150, with quarters and all found.

CHESHIRE, CROSSLEY SANATORIUM, Delamere Forest.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with rooms, board, washing, and attendance. Also Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

CROYDON GENERAL HOSPITAL.—Senior and Junior House Surgeons. Salaries £105 and £60 per annum respectively, with board, laundry, [illegible]

[illegible] —Principal County School Medical [illegible] and £65 per annum for travelling [illegible] ant School Medical Officer. Salary £150 per annum and £65 per annum for travelling and other expenses.

DUBLIN, ROYAL HOSPITAL FOR INCURABLES, Donnybrook.—Resident Medical Officer, unmarried. Salary £120 per annum, with board and apartments.

EXMINSTER, DEVON COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £150 per annum, rising to £200, with board, apartments, and laundry.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

HASTINGS EDUCATION COMMITTEE.—School Medical Officer. Salary at rate of £200 per annum.

CLINICAL CONTRIBUTIONS.

Beyond the discussion upon the relation of bovine and human tuberculosis, the main trend of the Congress concerned the sociological aspect of tuberculosis. There were, however, several interesting contributions in the clinical sections, the most novel perhaps being that of Army-Surgeon WRIGHT before Section II. It was an account of the treatment of over 60 cases by intramuscular injections of the salts of mercury, to which he was led by the amelioration of the pulmonary lesions in two cases which he had treated for secondary syphilis. The remarkable rapidity of the retrogression of the disease in these men led Dr. Wright to try the treatment in non-syphilitic consumptives. His success was nearly uniform, even advanced cases improving rapidly, and laryngeal lesions constantly disappearing. It does not appear possible to gainsay Dr. Wright's observations, although former clinical experience indicated that subjects of tuberculosis bore mercury badly. It is possible, however, that this intolerance may have been due to digestive disturbances caused by mercurial ingestion *viâ* the mouth preventing the high nutrition required by consumptives; and, moreover, the hygienic conditions under which consumption was formerly treated were not of the tonic character needed to enable mercury to act beneficially. Further trial, of course, is required before scepticism is allayed, but Dr. Wright's discovery seems to be an exceedingly valuable therapeutic advance.

Another valuable addition to our armament was contributed by Dr. G. BECK (Chicago) in Section III. He has devised a paste with which he keeps apart the granulating surfaces of tuberculous sinuses, by which means they heal without leaving the annoying residual foci which so usually cause relapses. The paste contains 33 per cent. of bismuth and thus affords a means of mapping out a sinus with the x rays. For cold abscesses a paste of 10 per cent. is used, being injected immediately after evacuation. This prevents secondary infections as well as keeping the surfaces apart. The clinical reports are exceedingly favourable.

In this, the surgical, section great emphasis was laid upon the nutritional adjuvants, and indeed sanatoriums for this purpose are now being erected in the United States.

In Section II. the discussion of sanatoriums was largely contributed to by the British representatives. The graduated labour method of the Brompton Hospital excited much interest. Great stress was laid on the undue cost to the community entailed by sanatoriums unless they are correlated with other agencies for the control of tuberculosis. Emphasis was laid upon the need of this in a lecture before the Washington Chamber of Commerce by Dr. R. W. PHILIP (Edinburgh), and an elaborate model was shown in the Maryland exhibit to illustrate the same point. With the medical officer of health for a centre, different coloured threads, centrifugal and centripetal, communicated with the general hospital, the family physician, the county poorhouse, the tuberculosis dispensary, and the special sanatorium respectively. The life insurance system which is in such successful operation in Germany was illustrated by a model of its large chain of sanatoriums and furnished clear explanations of the economic features of the plan. In a small way, though administered by a private association, the National Printers' Union furnished the same object-lesson by exhibiting a model of the annexe for tuberculosis of the Printers' Home in Colorado. The style of tent there used is now to be shown in the travelling exhibit of the American National Tuberculosis Association.

The results of sanatorium treatment were discussed by Dr. BROWN (Saranac). He presented statistics showing that out of 2553 patients, 1209 are known to be alive, of whom 1058 are able to work—that is, 87·5 per cent. He believes that these results are very encouraging.

An important adjuvant to the dispensary is presented by the experience of Dr. TOWNSEND (Boston) and Dr. WHITE (Pittsburg) who have planned respectively "day camps" and "night camps," and who discussed before Section II. their educational and economic value. These are now being imitated elsewhere and appear to be of great assistance to dispensaries.

The practical results of serum-therapy were contributed to in Section II. by a large number of workers, including Dr. FLICK (Pennsylvania), Dr. TRUDEAU (Saranac Lake, N.Y.), Dr. DENYS (Louvain), Dr. BÉRANECK (Neuchatel), and others. The collation of their work should afford additional guides for future practice but cannot be undertaken in a short contribution of this nature. In this section, too, the early use of the x ray for diagnosis of deep infiltrations was insisted upon by Dr. C. THEODORE WILLIAMS (London), Dr. RIST (Paris), and Dr. WILLIAMS (Boston).

A distinct therapeutic advance is the systematisation of diet schedules attempted by Dr. FISHER (Yale) and Dr. NEWTON (Mont Clair). The former investigated the diet used in 95 leading sanatoriums in the United States, Canada, Great Britain, France, Germany, Austria, Norway, Switzerland, and Russia. He finds that the food is usually given arbitrarily and does not differ from that used in neighbouring boarding-houses; that the number of calories varies from 2100 to 5500; and that the amount of protein differs as widely. He concludes that 3000 calories, of which only 10 per cent. should be protein, are ample for an ordinary consumptive; that an excess is injurious on account of the intestinal putrefaction which results, especially in the case of meat, on account of the waste products therein contained. Dr. Newton emphasised the reaction against the "stuffing" treatment formerly in vogue.

In the section of Children's Diseases Dr. WOODS-HUTCHINSON (New York) expressed his belief that even in infants the lung is the most frequent site of tuberculous involvement and that pulmonary tuberculosis is much commoner in them than was formerly believed. He believes the gland and bone involvements to be secondary. Dr. WOLLSTEIN (New York) as a result of 1131 necropsies, of which 185 were tuberculous, expressed the same belief.

The subject of the children of the tuberculous and their infection and relative immunity was discussed from different points of view by Dr. WARTHIN (Ann Arbor), who believed that the bacilli might traverse the placenta without causing lesions there. But Dr. FLOYD and Dr. BOWDITCH (Boston), as a result of a study of 900 children who had been exposed to home infection, concluded that contagion is a more important factor than heredity.

Dr. VON PIRQUET (Vienna) proposed the formation of an international statistical record on the basis of his cutaneous reaction, the cases being divided into those of (1) early reaction, signifying recent infection; (2) secondary reaction, signifying old or latent infection; and (3) no reaction (uninfected).

Dr. TEISSIER (Lyons) believed, as a result of his studies of intermittent albuminuria of childhood, that these cases were often due to the transmission to the fœtal kidney of the tuberculous toxin of an infected parent. "This produces," he said, "a slight degree of latent nephritis which results in a very relative impermeability, revealing itself in a moderate diminution of the total molecular diuresis, an increase in the coefficient of Korany, and also in a slight elevation of the blood pressure, a moderately severe albuminuria, usually intermittent, either of the matinal (morning) type, or frankly orthostatic (present during the active hours of the day); and finally, as the hall-mark of its tuberculous origin, a well-defined Arloing-Courmont serum reaction often exceeding 1/15." 34 per cent. of cases of intermittent albuminuria were of this type. They did not become tuberculous and were thus distinguished from the pre-tuberculous albuminuria, which disappeared as the lesions became evident. They were examples of the spontaneous immunisation to which Courmont had drawn attention.

Mrs. NOBLE (New York) referred to the importance of the control of respiration by the instinctive functioning of the afferent nerves of the respiratory system, including the olfactory; and pointed out how the vitiation of this reflex by foul air prevented the proper development of the chest by the deep breathing required for it. She proposed to found a league for popular prevention of nasal and pulmonary troubles in children.

Cattle and Tuberculosis.

In Section VII. many valuable data were presented regarding the control of animal tuberculosis with special emphasis upon the economic aspect. Dr. MELVIN, of the United States Bureau of Animal Industry, estimated at over $2,382,000 the loss due to the destruction of meat-producing animals as a result of Federal inspection. He believed that a further $2,000,000 would be lost if all the animals were inspected and that the stock was rapidly diminishing in value. The loss from disease in milk production was estimated at $1,150,000. The aggregate from all sources he estimated at $14,000,000. He advocated the system of tagging, and for will be *gradual. There is no subject upon which the crank and* faddist are more rampageous than on diet and it would be quite possible *for a few* obstinate, if honest and noisy, persons to bring the whole association under the *critical eye of that very section* of the public—viz., the medical and educational professions—whose sympathy it is their object *to enlist.*

◆

Mr. Edward Gamall.—Our correspondent is very fierce but also very *vague. He alleges* all forms of avaricious, mercenary, and dishonest conduct but gives no example. He talks of a Court of Appeal to set these matters right but make no attempt to suggest what sort of a court he *means. If he* means a court composed of leading men of the medical *profession how does* he reconcile his proposal with his statement that it is the leading men who *are disloyal* to each *other?*

Fumeur.—1. No. 2. It is immaterial. 3. Many patent pipes are used by many different *people* with advantage, but, on the other hand, many smokers derive no harm from neglecting these devices. 4. A smoker is able to find out for himself what tobacco suits *him.*

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—J. Lewin Payne, H. W. Trewby, D. P. Gabell): at 8 P.M.

Paper:

Mr. J. F. Colyer: Notes on the Etiology of Irregularities of the Teeth (illustrated by the epidiascope).

Specimen:

Mr. G. W. Thomson: Dog's Skull showing Result of Alveolar Abscess.

Communication:

Mr. Philip Turner: The Treatment of a Denture impacted in the Œsophagus, by means of Kilian's Œsophageal Tubes.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Herbert P. Hawkins, A. M. Gossage): at 5.30 P.M.

Papers:

Dr. Herringham and Dr. Wornack: The Resistance of Arteries to External Pressure. Experiments on the Value of the Sphygmomanometer as a Test of the Blood Pressure.

Dr. C. J. Macalister and Dr. H. C. Ross: On a Stimulant for the Leucocytes of Healthy Persons in the Blood-plasma of Patients suffering from Carcinoma.

[illegible]HURSDAY.

SPECIAL MEETING OF FELLOWS OF THE SOCIETY: at 5 P.M [illegible] Nov. 18th): [illegible] on Disease, with Special Reference to [illegible], and Diseases of the Nervous System.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Hugh Lett, E. I. Spriggs, Harold J. Stiles): at 5 P.M.

Papers:

Dr. Cecil E. Finny: Duodenal Ulcer with Perforation in a Child Two Months old (with specimen).

Mr. Duncan C. L. Fitzwilliams: *A Case of Congenital Scoliosis.*

Specimens:

Dr. Edmund Cautley: Congenital Morbus Cordis (two specimens).

Dr. George Carpenter: (1) Congenital Dilatation of the Colon in a Child of Six Months; (2) Septic Meningitis and Cerebral Hæmorrhage in an Infant.

Cases:

Mr. H. M. Rigby. A Case of Ectopia Vesicæ in a Child of Fourteen Months treated by Implantation of the Ureters into the Rectum.

Mr. Sydney Stephenson: A Case of Ptosis Adiposa (Blepharochalasis) in a Child of Seven Years.

Dr. G. A. Sutherland: (1) A Case of Cirrhosis of the Liver; (2) *A Case of Muscular Hypotonus.*

Dr. George Ca[illegible] lysis; (2) [illegible] associated [illegible]

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper:

Dr. William Butler: The Intermittent Infectiousness of Scarlet Fever.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. W. H. Battle: Recurrence after the Operation for Radical Cure of Inguinal Hernia.—Mr. V. W. Low: Report of Two Cases of Hæmorrhage into the Testicle of Doubtful Origin.

MEDICO-LEGAL SOCIETY, 22, Albemarle-street, W.

TUESDAY.—8.15 P.M., Exhibition of Specimens and Narration of Cases. Dr. A. G. Bateman: *Unqualified Practice* and the Medical Act of 1858.

HUNTERIAN SOCIETY.

WEDNESDAY.—8.30 P.M., Dr. C. Thomson: Demonstration on the Bioscope in Medicine.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Mr. E. M. Corner: The Indications of Suppuration in Appendicitis.—Mr. M. F. Kelly: The Treatment of *Urethral Stricture.*

CHILD STUDY SOCIETY LONDON, Parkes Museum, Margaret-street, W.

THURSDAY.—8 P.M., Dr. G. E. Pritchard: Physiology of the Child.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' *COLLEGE AND* POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. W. *Fox: Clinique (Skin). 5.15* P.M., Lecture:—Mr. M. Yearsley: Stammering.

TUESDAY.—4 P.M., Dr. W. Carr: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. P. Luff: The Uses of the Calcium Salts in *various* Morbid Conditions.

WEDNESDAY.—4 P.M., Mr. J. Cantlie: Clinique (Surgical). 5.15 P.M., *Lecture:—Dr. C. Mercier: Some Interesting Mental Conditions* (with cases).

appears that a farmer who sells "fore milk" renders himself liable to prosecution for deficiency of fat, 3 per cent. being the limit set by the Board of Agriculture.

Hospital Saturday Collections at West Bromwich.

The total amount raised during the year was £2207, of which £2153 were paid to the hospital. This is a slight advance upon the previous year. There were increased subscriptions from the works in the district, the Wednesbury Committee also collected a larger amount than in previous years, and there would have been a much better result than that actually obtained had it not been that the receipts from the charity sports fell much beneath expectations.

Nov. 17th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine.

ON Saturday last, Nov. 14th, the twenty-first expedition of the Liverpool School of Tropical Medicine left Bristol for Jamaica by the s.s. *Port Henderson* belonging to the Imperial Direct West India Mail Service Co., Limited. The expedition consists of Mr. R. Newstead, M.Sc., A.L.S., F.E.S., lecturer in economic entomology in the University of Liverpool, and Dr. W. T. Prout, C.M.G., late principal medical officer of Sierra Leone. Later the expedition will be joined by Mr. A. H. Hanley, C.M.G., late principal medical officer, Southern Nigeria. The objects of the expedition are twofold, as it is partly medical and partly entomological. Mr. Newstead will undertake the following duties: 1. To study the bionomics of cattle ticks and to advise some methods of control. 2. To undertake the investigation of those scale insects which are at the present moment threatening the citrus and cocoa and coco-nut cultivation in the Island of Jamaica, and to advise some method of control. 3. To make a collection of the biting flies and ticks of the island for the use of students attending the course of instruction at the Liverpool School of Tropical Medicine. Dr. Prout and Mr. Hanley will investigate the following points—viz.: 1. The prevalence of filaria in Jamaica. 2. The prevalence of malaria in especially malarious districts of the island. 3. Measures for prevention of mosquito-borne diseases where feasible. 4. Preliminary investigation into the so-called "vomiting sickness" amongst children. Sir Alfred Jones entertained Dr. Prout and Mr. Newstead at luncheon a few days before the expedition started, a large party being present, among whom were Sir Henry Blake, ex-Governor of Jamaica, Sir Edward Evans, Sir Rubert W. Boyce, and Professor Ronald Ross. During the luncheon a telegram was received from Colonel Seely, wishing the expedition all success.

Lancashire's Birth-rate: the Lowest on Record.

The lowest birth-rate on record, reduced infant mortality, and a lower general death-rate are the leading features in the annual report of Mr. E. Sergeant, medical officer of health of Lancashire. The death-rate of the year 1907 was 14·4 per 1000 of the population, which is fractionally less than in 1906 and 1·6 below the average for the ten years 1897–1906. The infant deaths under one year were 125 per 1000 births, a decrease from 139 in the previous year, the average for the ten years being 154. Although a falling birth-rate is usually accompanied by a reduced infant mortality evidence is not wanting that conditions affecting infant life, both in the home and home surroundings, are much better than a few years ago. The birth-rate, equal to 24·23 per 1000 of the population, is the lowest recorded and shows a decrease of 0·76 compared with 1906 and 2·34 compared with the ten years 1897–1906. The birth-rate of the county is 2·1 per 1000 below the rate for England and Wales.

Plague in Liverpool.

At a meeting of the health committee held on Nov. 12th the chairman, referring to the cases of plague which had occurred in the city, assured the citizens that they could rest content that the port sanitary authority was doing everything possible to arrest the spread of the disease. It was a matter of great importance to the port. He had been in touch with the medical officer of health and the disease was being carefully watched. The disease had been practically confined to one coal barge and he stated that the port appeared to be now quite safe and out of danger. Last year the death-rate of the city was low and this year he thought it would be a shade lower.

Sir William Hartley and the Municipal Treatment of Tuberculosis.

Speaking at a dinner in honour of Alderman Menlove, the chairman of the health committee, held on Nov. 12th, Sir William Hartley made a strong plea for the municipal treatment of tuberculosis, and advocated the provision of a sanatorium for working-class patients from Liverpool and the provision of a fund for maintaining the families of working men while under curative treatment in an early stage of the disease. Towards such a fund he offered to subscribe £5000 provided an additional £10,000 were subscribed within a reasonable time when the scheme was matured.

The Hospital Saturday and Sunday Funds.

The Liverpool Hospital Saturday and Sunday Funds have made their final apportionment of the 1907-08 collections, the sums, which are supplementary to earlier distributions, ranging from £1240 to the Royal Infirmary to £14 19*s.* to the St. George's Skin Hospital. The total of the present contributions is just short of £6000, the earlier distributions amounting to £10,000. The total amounts contributed to the various hospitals reached the sum of £15,980.

Nov. 17th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Sir Thomas Oliver.

Dr. Thomas Oliver will be most heartily congratulated upon the conferment of the honour of a knighthood upon him by the King. Dr. Oliver's work in connexion with industrial diseases was specially mentioned by the King in his speech at the opening of the new buildings of the Royal Infirmary on the Town Moor in July, 1906, and the present further acknowledgment of the position held by Sir Thomas Oliver in that branch of medical science will be received by all who know him or his work with very great pleasure and satisfaction. I cannot refrain also from congratulating the College and infirmary upon the fact that the work of two of their members has within so short a space of time been recognised in so signal a manner, for it is but a couple of months since Professor George R. Murray left this city to accept the invitation of Manchester to occupy the chair of medicine in its University. The honour which Sir Thomas Oliver has now received at the hands of the King, coupled with the recognition given to his work by the profession in selecting him as the President of the Section of Industrial Diseases at the last meeting of the British Medical Association at Sheffield, also raises another point—viz., the question of the teaching of industrial diseases. This branch of medical knowledge is almost, if not entirely, ignored in the ordinary course pursued by the student reading for his qualifications to practise medicine, and that in spite of the fact that, in the large industrial towns at least, a large part of the disease which the general practitioner is called upon to treat is, now that the "zymotic" diseases are cared for by the State, more or less directly connected with the occupation followed by the patient. The time has certainly arrived when the influence of occupation upon the health of the worker should be more closely studied and the results already obtained made more readily accessible to those entering the profession. I wish that Newcastle with its unrivalled facilities for the study and teaching of the diseases of occupation could set an example in this direction and institute a department of industrial diseases. Such a step would not only be an indication that the University is alive to its opportunities but would also be for the very material welfare of those who form the vast bulk of the population of the district.

The University of Durham Act, 1908.

Mr. J. Bruce Williamson, barrister-at-law, has been gazetted as secretary to the Commissioners appointed under this Act, of whom the Duke of Northumberland is chairman.

delusional insanity in whom recovery was hopeless. The Gartloch recovery rate of 39·6 per cent. is well above that of the Scottish Royal and District Asylums. As usual, alcohol is reported as appearing to be the factor in more cases than any other cause. Parental drunkenness is also a striking cause.

Death of Mr. John Dougall, M.D. Glasg., F.F.P.S. Glasg.

The death of Dr. John Dougall took place at Glasgow on Nov. 14th. Dr. Dougall studied at the University of Glasgow and graduated M.B., C.M. in 1869 and M.D. two years later. He became a Fellow of the Faculty of Physicians and Surgeons of Glasgow in 1876, and afterwards was appointed lecturer in materia medica in the school of medicine of Glasgow Royal Infirmary, and when that school was transformed into St. Mungo's College he retained the position and occupied it until the time of his death. For many years he was one of the visiting physicians of the Royal Infirmary, an office from which he retired five years ago. Subjects to which he directed special attention were the possibility of manufacturing vaccine apart from animals and the methods of disinfection. He also wrote a number of verses which were published in book form. He was a keen lover of nature, and was a member of both the Geological and Natural History Societies of Glasgow.

Bequests for Paisley Infirmaries.

Under the will of the late Mr. Samuel Young of Paisley local infirmaries have benefited considerably. The Royal Alexandra Infirmary Endowment Fund gets £600 and the building fund £400, the Royal Victoria Eye Infirmary gets £400, and the Paisley and District Association for the Prevention of Consumption and other Forms of Tuberculosis £200.

University of Aberdeen: Appointment to the Chair of Pathology.

As announced in THE LANCET last week the King has been pleased, upon the recommendation of the Secretary for Scotland, to appoint Mr. George Dean, M.B., C.M., chief bacteriologist at the Lister Institute of Preventive Medicine, to the chair of pathology in the University of Aberdeen, vacant by the resignation of Professor D. J. Hamilton. Professor Dean, who is a native of Aberdeenshire, graduated M.A. at the University of Aberdeen in 1885 with honours in natural science, and M.B., C.M., with honours in 1889. After graduation he studied in Berlin under Professor Pfeiffer and Professor Virchow and in Vienna. In 1891 he was appointed assistant to Professor Hamilton in the University of Aberdeen and held this post until in 1897 he was appointed bacteriologist in charge of the serum department of the Lister Institute of Preventive Medicine. In 1906 Dr. Dean was promoted to the post of chief bacteriologist to the Lister Institute. He has acted as examiner in pathology at the University of Aberdeen and examiner in pathology and bacteriology at the Royal College of Veterinary Surgeons. He has published numerous papers dealing with research on diphtheria, tetanus, tuberculosis, plague, typhoid fever, and on various questions connected with immunity. The appointment has given great satisfaction in Aberdeen University circles.

The Treatment of Consumption in Aberdeen.

At the monthly meeting of the Aberdeen city parish council held on Nov. 10th, the adoption of a report by the poor-house committee was moved and seconded, which report recommended that the upper male and female wards at the south end of the general hospital at the poor-house should be set aside for the treatment of curable cases of consumption and for the isolation of more advanced cases; and that it be remitted back to the poor-house committee, with powers to carry out the necessary alterations of the wards at a cost not exceeding £190. An amendment was moved and seconded that "No further action be taken with this matter meantime." 19 voted for the adoption of the report and 9 against. The wards are capable of accommodating 20 male and 20 female patients, and the following alterations will require to be made: (*a*) the Plenum system of heating and ventilation shut off from both wards; (*b*) the heating carried out by steam radiators; (*c*) ventilation obtained by altering the windows to open by quadrants from the upper horizontal sash, with additional inlet ventilators through the walls at the rear of the radiators; and (*d*) the erection of a roof over the balcony at the south end of each ward.

Nov. [illegible]th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Government Grants to Dublin Hospitals.

AT a meeting of the South Dublin guardians on Nov. 11th the following motion was proposed by one of the members:—

> That in our opinion the time has come when the system of giving the Government grants to our city hospitals should be revised; that in future all our city hospitals should receive a share of the said grant in proportion to the number of poor people relieved and treated by them.

He also appended a suggestion that copies of the resolution should be sent to the Chief Secretary for Ireland, the Lords of the Treasury, and the various members of the Dublin corporation. He then proceeded to point out that the 269 beds of Cork-street Fever Hospital had, on an average, but 148 of these occupied. The number of patients during last year was 1997. There were no dispensary patients. The Government grant towards maintenance was £2500. In Steevens' Hospital there were 230 beds, and the average number occupied was 173. The number of intern patients during last year was 1566, and that of those treated in the dispensary was 13,804. The Government grant to this hospital was £1300. In the Meath Hospital there were 147 beds, and the average number occupied was 106. The intern patients last year amounted to 1446 and the dispensary cases to 16,463. The Government grant was £600. There were 97 beds in the Rotunda Hospital and the average number occupied was 71. The number of patients during last year was 2435; that of the dispensary cases 12,366. The Government contributed £700. In the Royal Hospital for Incurables there were 217 beds and the average number occupied was 207. During the past year the number of patients was 528 and the Government grant was £250. In the Mater Misericordiæ Hospital there were 335 beds and the average number occupied was 310. During the past year there were 3852 intern and 21,240 dispensary patients; while the Government made no contribution whatever to its maintenance. St. Vincent's Hospital had 145 beds and the average number occupied was 96. Last year there were 1847 intern and 20,539 dispensary patients and there was no Government grant. The Holles-street Hospital had 46 beds, of which the occupied average was 36. The intern patients during the past year numbered 828 and the dispensary cases 4285. Again no Government grant. The Hospice for the Dying had 110 beds, of which the average number occupied was 96. There was no Government grant. The case was surely one for re-adjustment. The motion was duly seconded and carried. All readers must agree that in a democratic age the influences of social ascendancy, religious bigotry, racial antipathy, and political jobbery should not be allowed to hamper facilities in the treatment of the sick and suffering, which are always cheerfully afforded by a sympathetic and charitable public. That they have done so in Ireland cannot be denied; it is also obvious that they cannot long continue to do so.

Anti-Tuberculosis Crusade: the Progress of the "Lecture Van."

A "tuberculosis caravan," which has been provided by the committee of the Women's National Health Association of Ireland, is visiting various parts of the country, and lectures will be delivered on the best method of combating consumption by the accompanying medical man. The opening ceremony took place at Kilcool, county Wicklow, in the presence of a large gathering of the inhabitants. From Kilcool it moved to the more important centre of Newtownmountkennedy. Lady Aberdeen paid a formal visit to this station on Nov. 10th and was received in the school-house by a representative gathering of local gentry and others. The chair was occupied by the Rev. Canon Drought. Miss Tottenham, president of the local subcommittee of the Women's National Health Association, was present, with a large number of the members. Loud and hearty greetings followed Her Excellency's entrance into the school-room and the chairman expressed the general appreciation of her exertions "in pursuance of her great crusade against the terrible ravages of tuberculosis." Father Duggan pointed out that "the work that had been done was already bearing fruit in the district because he saw in Kilcool the day before that many of the windows of the houses were open"—a statement which being thereby put into a position to take up more sugar than it might otherwise do.

The bearings connected with the

DISPOSAL OF CARBOHYDRATE BY SYNTHESIS INTO PROTEIN

at the seat of absorption have been fully discussed in my "Carbohydrate Metabolism and Diabetes" already referred to (*vide* pp. 54 to 64). The lymphocyte is the agent concerned in the process, and the method by which the synthesis is effected is by bioplasmic growth. It is known that, in the mucous membrane of the intestine, there is a very active growth and renewal of lymphocytes carried on in concurrence with the absorption of the products of digestion. The rôle of the lymphocyte found in this situation is to grow upon the absorbed material supplied to it from the food. As occurs in conformity with a general law applying to living matter, the bioplasmic molecules take to themselves, from the molecules around, those of suitable configuration for being linked on by the combining influence of affinity. Thus the sugar molecules become built into the newly formed protein complex, and in this state are carried, within the lymphocyte, into the circulatory system.

What next occurs is that the lymphocytes undergo autolysis. Proof is afforded that this phenomenon actually takes place by the fact of the systematic disappearance that is noticeable after their entry into the blood. Accompanying each intake of food, there is a flow of lymphocytes into the circulatory system, which is followed by a subsidence till a fresh intake of food occurs. Thus is afforded a source for the fibrinogen, globulin, and albumin of the blood. It cannot be conceived that these bodies arise otherwise than through the medium of a preceding bioplasmic formation, and viewed in this way, the phenomena, as I have shown in the work referred to, not only receive the support of observation, but fit in consistently with the line of procedure that meets what is wanted in connexion with the matter. Locked up in the protein constituents of the blood in the manner depicted, the sugar molecule derived from the food is placed in a position to be transported from the seat of absorption to that of utilisation without running off with the urine.

I have been speaking about the course taken by the carbohydrate portion of the food, and it is interesting to note

THE CLOSE ANALOGY THAT EXISTS

between what occurs in connexion with this portion of the food on the one hand, and the nitrogenous portion on the other. With both, the first step is to place them, by enzyme action within the alimentary canal, into a suitable state for absorption and subsequent bioplasmic incorporation. I strongly hold the opinion which I urged in my "Physiology of the Carbohydrates" published in 1894, that what next occurs, as well for the products of digestion coming from the nitrogenous principles of food as for those coming from carbohydrate matter, is their assimilation, or re-synthesis, at the seat of absorption, into the proteins that are destined to be transmitted through the absorbent system to become proteins of the blood.

In former times, it was considered that it sufficed for the breaking-down process by enzyme action to be carried as far as the stages of albumose and peptone,—the extent to which it is carried by pepsin, and to which it is in the main carried by trypsin. Latterly, however, the view has sprung up that hydrolysis is carried to the production of the amino-acids; erepsin, which is discoverable in the mucous membrane of the intestine, being the agent that possesses the power of accomplishing this supplementary work. Cohnheim,[2] after showing the existence of erepsin in the mucous membrane of the intestine, speaks of it as holding an analogous position in connexion with protein digestion to that held by glucase in connexion with starch digestion. Whilst the latter, it is said, hydrolyses maltose, derived from the action of diastase, into glucose, erepsin hydrolyses the albumose and peptone, resulting from the peptic and tryptic digestion of protein, into the amino-acids, and in keeping with this view, it is stated to be found that health and nitrogenous equilibrium are capable of being maintained in animals fed upon these products in place of the parent protein.

What is wanted is that the molecules produced, whatever they may be, should be of a configuration to render them susceptible of being

TAKEN ON BY THE BIOPLASMIC MOLECULAR COMPLEX

in which the metabolic action at the foundation of the phenomena of life occurs. In the language of the side-chain theory, bioplasm consists of complex molecules, made up of a functioning centre provided with innumerable arms or side-chains with ends of various configurations adapting them for junction with suitably constructed food-stuff and other molecules. It is within the atomic groupings thus put together that the interactions occur that give rise to oxidation, and thence the development of the various manifestations of energy observed to take place. The theory involves the entry and storage of oxygen in the molecular complex, as well as the oxidisable materials, and as the two become used up, they are replaced by a fresh taking on. With arms having full-up side-chains tacked on, no capacity exists for the taking-on of outside food-stuff molecules, a state of things that may be likened to that which exists in connexion with the chemistry of the inorganic or non-living kingdom of Nature. A compound with its bonds of union in a satisfied state is not in the position for the occurrence of further linking-on, but with free or unsaturated bonds, linkage can occur with anything that is suitably conditioned for being taken on.

Food-stuff molecules, then, require to be incorporated within the bioplasmic molecules of the different components of the body as a preparatory step to subjection to utilisation. What actually takes place after entry into the molecule is, at present, altogether beyond our power of forming a conception. It is evident, however, from the products met with that there must indeed be a very complicated play of changes occurring. Whilst without cognisance of what in detail is going on within, we can nevertheless frame an idea of the general actions taking place by giving attention to the bodies that go in and those that come out. Besides oxidations, hydrolyses, and condensations, the capacity for re-groupings exists, rendering the entry of one body, as for instance a carbohydrate, and the exit of another, as for instance fat, in like manner to what occurs upon a more simple scale in the case of enzyme action, intelligible. Apparently, in

THE FUNCTIONING OF THE MOLECULAR COMPLEX,

side-chains taken on may be afterwards worked off and renewed without the disruption of the centre of the molecule, whilst circumstances may exist to conduct on to the occurrence of a full breaking-down.

The close parallelism that exists between starch and protein in relation to the course of events noticeable in connexion with their application as food principles, is exceedingly striking. They both become hydrolysed and broken down in a corresponding way by enzyme action to fit them for absorption, and for being subsequently taken on by, and incorporated into, the bioplasmic molecule wherein the metabolic actions occur that give issue to the phenomena of life. I think all are now agreed upon the point that entry of the food-stuff molecule, whatever its nature, into the bioplasmic complex is a necessary step towards utilisation, and this being the case, the preliminary procedures in reality merely make provision for the accomplishment of the end to be attained.

The knotty point connected with the subject now presents itself for consideration.

IN WHAT STATE DOES THE FOOD-SUPPLY TRAVEL

from the seat of absorption to that of utilisation in the tissues? I have put the question in a plainly expressed form, and it requires to be frankly met. Under the old view, certainly as regards carbohydrate, the absorbed material was looked upon as being transported through the circulation in an unchanged or free molecular state. I have shown how such a state of things is inconsistent with escape from running off with the urine during the passage of the blood through the kidney, as occurs in connexion with diabetes. Upon the principle of a similar line of action, it has been said of protein, since attention has been given to erepsin, that digestive disruption is carried to the amino-acids, and that it is by the transport of these in a free state through the circulation that the tissues obtain their nitrogenous nutrient supply. If such occurred, the urine ought to reveal it in the same manner as with sugar. We know, when a pathological source for leucine, tyrosine, &c., exists, that they readily enough find their way into the urine, and what is to keep them back if they passed through the circulation for the purpose of transmitting nitrogenous material from the food to the tissues. Even much larger molecular bodies than the amino-acids pass into the urine if they reach the delusional insanity in whom recovery was hopeless. The Gartloch recovery rate of 39·6 per cent. is well above that of the Scottish Royal and District Asylums. As usual, alcohol is reported as appearing to be the factor in more cases than any other cause. Parental drunkenness is also a striking cause.

Death of Mr. John Dougall, M.D. Glasg., F.F.P.S. Glasg.

The death of Dr. John Dougall took place at Glasgow on Nov. 14th. Dr. Dougall studied at the University of Glasgow and graduated M.B., C.M. in 1869 and M.D. two years later. He became a Fellow of the Faculty of Physicians and Surgeons of Glasgow in 1876, and afterwards was appointed lecturer in materia medica in the school of medicine of Glasgow Royal Infirmary, and when that school was transformed into St. Mungo's College he retained the position and occupied it until the time of his death. For many years he was one of the visiting physicians of the Royal Infirmary, an office from which he retired five years ago. Subjects to which he directed special attention were the possibility of manufacturing vaccine apart from animals and the methods of disinfection. He also wrote a number of verses which were published in book form. He was a keen lover of nature, and was a member of both the Geological and Natural History Societies of Glasgow.

Bequests for Paisley Infirmaries.

Under the will of the late Mr. Samuel Young of Paisley local infirmaries have benefited considerably. The Royal Alexandra Infirmary Endowment Fund gets £600 and the building fund £400, the Royal Victoria Eye Infirmary gets £400, and the Paisley and District Association for the Prevention of Consumption and other Forms of Tuberculosis £200.

University of Aberdeen: Appointment to the Chair of Pathology.

As announced in THE LANCET last week the King has been pleased, upon the recommendation of the Secretary for Scotland, to appoint Mr. George Dean, M.B., C.M., chief bacteriologist at the Lister Institute of Preventive Medicine, to the chair of pathology in the University of Aberdeen, vacant by the resignation of Professor D. J. Hamilton. Professor Dean, who is a native of Aberdeenshire, graduated M.A. at the University of Aberdeen in 1885 with honours in natural science, and M.B., C.M., with honours in 1889. After graduation he studied in Berlin under Professor Pfeiffer and Professor Virchow and in Vienna. In 1891 he was appointed assistant to Professor Hamilton in the University of Aberdeen and held this post until in 1897 he was appointed bacteriologist in charge of the serum department of the Lister Institute of Preventive Medicine. In 1906 Dr. Dean was promoted to the post of chief bacteriologist to the Lister Institute. He has acted as examiner in pathology at the University of Aberdeen and examiner in pathology and bacteriology at the Royal College of Veterinary Surgeons. He has published numerous papers dealing with research on diphtheria, tetanus, tuberculosis, plague, typhoid fever, and on various questions connected with immunity. The appointment has given great satisfaction in Aberdeen University circles.

The Treatment of Consumption in Aberdeen.

At the monthly meeting of the Aberdeen city parish council held on Nov. 10th, the adoption of a report by the poor-house committee was moved and seconded, which report recommended that the upper male and female wards at the south end of the general hospital at the poor-house should be set aside for the treatment of curable cases of consumption and for the isolation of more advanced cases; and that it be remitted back to the poor-house committee, with powers to carry out the necessary alterations of the wards at a cost not exceeding £190. An amendment was moved and seconded that "No further action be taken with this matter meantime." 19 voted for the adoption of the report and 9 against. The wards are capable of accommodating 20 male and 20 female patients, and the following alterations will require to be made: (*a*) the Plenum system of heating and ventilation shut off from both wards; (*b*) the heating carried out by steam radiators; (*c*) ventilation obtained by altering the windows to open by quadrants from the upper horizontal sash, with additional inlet ventilators through the walls at the rear of the radiators; and (*d*) the erection of a roof over the balcony at the south end of each ward.

Nov. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Government Grants to Dublin Hospitals.

AT a meeting of the South Dublin guardians on Nov. 11th the following motion was proposed by one of the members:—

> That in our opinion the time has come when the system of giving the Government grants to our city hospitals should be revised; that in future all our city hospitals should receive a share of the said grant in proportion to the number of poor people relieved and treated by them.

He also appended a suggestion that copies of the resolution should be sent to the Chief Secretary for Ireland, the Lords of the Treasury, and the various members of the Dublin corporation. He then proceeded to point out that the 269 beds of Cork-street Fever Hospital had, on an average, but 148 of these occupied. The number of patients during last year was 1997. There were no dispensary patients. The Government grant towards maintenance was £2500. In Steevens' Hospital there were 230 beds, and the average number occupied was 173. The number of intern patients during last year was 1566, and that of those treated in the dispensary was 13,804. The Government grant to this hospital was £1300. In the Meath Hospital there were 147 beds, and the average number occupied was 106. The intern patients last year amounted to 1446 and the dispensary cases to 16,463. The Government grant was £600. There were 97 beds in the Rotunda Hospital and the average number occupied was 71. The number of patients during last year was 2435; that of the dispensary cases 12,366. The Government contributed £700. In the Royal Hospital for Incurables there were 217 beds and the average number occupied was 207. During the past year the number of patients was 528 and the Government grant was £250. In the Mater Misericordiæ Hospital there were 335 beds and the average number occupied was 310. During the past year there were 3352 intern and 21,240 dispensary patients; while the Government made no contribution whatever to its maintenance. St. Vincent's Hospital had 145 beds and the average number occupied was 96. Last year there were 1847 intern and 20,539 dispensary patients and there was no Government grant. The Holles-street Hospital had 46 beds, of which the occupied average was 36. The intern patients during the past year numbered 823 and the dispensary cases 4285. Again no Government grant. The Hospice for the Dying had 110 beds, of which the average number occupied was 96. There was no Government grant. The case was surely one for re-adjustment. The motion was duly seconded and carried. All readers must agree that in a democratic age the influences of social ascendancy, religious bigotry, racial antipathy, and political jobbery should not be allowed to hamper facilities in the treatment of the sick and suffering, which are always cheerfully afforded by a sympathetic and charitable public. That they have done so in Ireland cannot be denied; it is also obvious that they cannot long continue to do so.

Anti-Tuberculosis Crusade: the Progress of the "Lecture Van."

A "tuberculosis caravan," which has been provided by the committee of the Women's National Health Association of Ireland, is visiting various parts of the country, and lectures will be delivered on the best method of combating consumption by the accompanying medical man. The opening ceremony took place at Kilcool, county Wicklow, in the presence of a large gathering of the inhabitants. From Kilcool it moved to the more important centre of Newtownmountkennedy. Lady Aberdeen paid a formal visit to this station on Nov. 10th and was received in the school-house by a representative gathering of local gentry and others. The chair was occupied by the Rev. Canon Drought. Miss Tottenham, president of the local subcommittee of the Women's National Health Association, was present, with a large number of the members. Loud and hearty greetings followed Her Excellency's entrance into the school-room and the chairman expressed the general appreciation of her exertions "in pursuance of her great crusade against the terrible ravages of tuberculosis." Father Duggan pointed out that "the work that had been done was already bearing fruit in the district because he saw in Kilcool the day before that many of the windows of the houses were open"—a statement which

"Handbook of Physiology" (1907) we find it stated under the head of *Absorption of Proteins* (p. 530):—"The normal course of events is that the food proteins are broken up into their constituent amino-acids, and it is in this form that they are absorbed ...... Not many years ago it was held that proteins were mainly absorbed as peptone, and that the absence of proteoses and peptones in the stream was due to the fact that the intestinal epithelium had the power of re-synthesising the blood proteins from the peptones ...... Recent research has failed to substantiate such views, and the intestinal epithelium does not possess the exclusive power of building up heavy moleculed proteins either from 'peptones' or from amino-acids ...... There is something very attractive in this view, because it affords a rational explanation of why it is that the organism can construct the proteins peculiar to itself and maintain its chemical individuality, although the food taken varies so widely in composition."

What ground is there for this change of opinion? Is there any real justification for it? Recent research, it is said, has failed to substantiate the old view. Has it done anything, it may be asked, to substantiate the new? There is absolutely nothing beyond pure conjecture to deal with, and I protest against the acceptance of any view that implies the passage of nutrient matter through the circulation in a form to be susceptible of filtering off with the urine. Nature does not operate in such a defective way, and food put into a small molecular state for transit through the system could not be prevented, to a greater or less extent, from passing off as waste material with the urine.

Professor Halliburton seems to have been influenced by the attractiveness of the success that has attended Emil Fischer's

EFFORTS TO SYNTHESISE AMINO-ACIDS

into poly-peptides, which may be spoken of as the lower grades of protein. Because the chemist, however, can only, as yet, synthesise members of the amino-acid group of cleavage products of proteolysis into higher combinations, it is not to be argued that Nature is in the same position. In our laboratory procedures we lack the power of forging the implements that Nature in her building-up and breaking-down operations works with. When we get hold of and employ these implements—as, for instance, when we operate with enzymes—we can achieve in our laboratory experiments the same that is effected within the living organism.

It may be taken that chemistry works upon the same lines inside and outside living matter. Affinity and adaptability in molecular configuration are at the root of chemical union. If molecules are not of suitable configuration for linkage together, no chemical union can occur. It is intelligible that with molecules of simple construction adaptability for union rests upon a less complicated basis than with molecules of a complex nature. Thus, with the more simple molecules the required conditions for union may be susceptible of being found and supplied, whilst in the case of the more complicated ones our efforts may prove altogether fruitless. A complicated lock is as easily opened as a simple one if a right-fitting key is at hand for the purpose. Here lies the pith of the matter. There is far more difficulty in meeting with the right key for the complicated than there is for the simple lock.

If peptone as a product of proteolysis can be taken on, through the agency of the enzyme concerned in the synthetic operation, by the molecular complex of the living cell, there is no need for proteolysis to proceed further. Nature, with her enzyme, may be able to provide the requisite adaptability for union, whilst the laboratory worker, unsupplied with the enzyme, may be unable to do so. Working, however, with a more simple form of molecule, it is only natural to conclude that a greater possibility of success may present itself. It is only in this way, as far as I can see, that advantage is likely to be derivable from a more complete proteolysis. What is wanted to be attained is that the protein food molecule should be broken down into fragments that are susceptible of being re-synthesised into the reconstructed protein entering into the constitution of the organism that receives the food.

The all-important point connected with this matter is the

SEAT AT WHICH THE RECONSTRUCTION OF THE BROKEN-DOWN FOOD MOLECULE OCCURS.

Professor Halliburton says that the reconstruction takes place in the tissue cells, the fragments from the food proteolysis being conveyed thither by the blood in the form of amino-acid molecules. I have upon many occasions referred to the effect of the transmission of small molecular bodies through the circulation in relation to the urine, and I hold that their entry into the blood is attended with their appearance in the urine, so that alike for sugar and for the amino-acids, appeal may be made to the urine to afford an indication of what stands good in connexion with the blood. No one disputes that a re-synthesis of the products of proteolysis occurs. The point is, Does it occur at the seat of absorption or does it occur in the tissues? In the first case, the re-united cleavage products reach the blood in the form of protein which escapes from passing into the urine. In the second, the passage of the disjoined products to the tissues ought to be made manifest through the medium of the urine.

Professor Halliburton reproves Abderhalden, a distinguished worker in association with Emil Fischer on the proteins, for not coinciding with him in the view that has been set forth, and for advocating instead, in a recently published paper, the view antecedently entertained that the products of protein cleavage are re-synthesised in the intestinal wall. In his "Annual Report on Physiological Chemistry for 1907," issued by the Chemical Society, the following words are, at p. 235, to be found: "Abderhalden's reactionary conclusion on the matter shows a lack of the acumen which is usually noticeable in his writings." Is it not possible that opinions may differ as to the side on which the lack of acumen lies?

I will now proceed to show that if we look broadly into the matter, tangible evidence can be adduced to show that production of protein must take place in connexion with food absorption at the actual seat of its occurrence in the walls of the alimentary canal. Persons seem, upon the point before us, to have been led away by narrow experimental considerations and to have overlooked the broad facts that confront us. No one can dispute that

A FLOW OF CHYLE TAKES PLACE

through the thoracic duct into the circulatory system concurrently with the digestion and absorption of food. Now, what does the flow that thus takes place imply? Let us see the nature of the answer to be given to the question.

Anatomy teaches us that the absorbent system consists of an elaborate set of vessels dispersed throughout all the tissues within the body. Starting from the lacunæ or spaces intervening between the capillaries of the vascular system and the tissue elements, the vessels join in a complicated manner and proceed to each side of the lower part of the neck where they discharge their contents into vessels belonging to the venous system. One office of the absorbent system may be stated to be to convey back into the blood-vessels materials which have escaped from the blood capillaries and have not been made use of by the tissues. The escape from the capillaries is found to fluctuate with the amount of blood pressure in them. In a state of rest, the pressure may be such as to lead to only an insignificant transudation occurring. As the pressure rises, both quantity and quality of the exudate, or lymph, become altered. The quantity is increased, and protein bodies, which in the absence of hydrostatic pressure are not transmissible through membranes, find their way, in proportion to the existing pressure, through the walls of the vessels into the lymph spaces. The lymph which occupies the interstitial spaces between the blood vessels and the tissue elements thus constitutes an exudate from the blood plasma varying in amount and character in an automatic manner according to the requirements of nutrition, for the conditions—tissue exercise, gland flow, &c.—which create an increased demand for nutrient supply, at the same time give birth to an increased capillary fulness involving increased capillary blood pressure.

The view that is here shaped into words represents that which is generally entertained, and it adequately serves to meet the facts that confront us in connexion with the matter. To the view that lymph production is the result of a secretory action of the endothelial cells of the capillary vessels, I give no credence. I am no believer in chemical and physical laws being set at naught in living beings and superseded by a mysterious supernatural "vital" agency, which, in the case before us, would lead up to exceedingly delicate and simply protective epithelial cells having a secreting function thrown upon them, and being employed in work which it is irrational to conceive could be accomplished and down stairs with ease and comfort. Dr. Delbet's method is as follows. Thanks to certain bearings which are carefully laid down by means of a special apparatus which he described, he can with certainty pass a pin or a screw through the neck of the femur into the head. The pins are well tolerated. General anæsthesia is unnecessary: a deep injection of stovaine is introduced into the field of fracture and a superficial one is given in the line of the incision.

Trouble at the Faculty of Medicine.

I have written from time to time in THE LANCET of the troubles which occurred last year at the Faculty of Medicine in connexion with the opening lectures of the new professors. Dr. Nicolas and Dr. Prenant. As a consequence of these disturbances the Faculty was shut for some weeks. At the beginning of November, when Dr. Nicolas began his present course of lectures, the students of the first and second years began their disturbances again. This time, however, they alleged different reasons. They no longer laid stress on the fact that Dr. Nicolas was provincial, but they argued: (1) That students could no longer go to Clamart to dissect; (2) that they got no good out of their work, for the authorities put seven men on to one body; and (3) that the post of chief demonstrator, which had been held by M. Rieffel, had been done away with at, they alleged, the instance of Dr. Nicolas. M. Landouzy, the dean of the Faculty, said in an interview that the reasons given were merely pretexts. The real reason why students were no longer allowed to go to Clamart is on account of the alteration in the law as to military service, which has led to there being far less overcrowding of students of medicine. Formerly every young man had to put in three years of military service except he were a student in law or medicine, when he only did one year. Now, however, the term of service is reduced to two years and there are no exceptions for students—a fact which has considerably diminished the crush. Clamart was simply struck off the list owing to the diminution in the number of students. As to seven students being set to dissect on each body, M. Landouzy said that in his time seven students were able to do excellent work on one body. As to the suppression of M. Rieffel's post, that was the act of the Council of the Faculty and had nothing to do with Dr. Nicolas. Finally, M. Landouzy said that if the disturbances went on he should not again close the Faculty, for that pressed hardly on students who were anxious to work, but he should simply prosecute in the ordinary courts anybody who had burnt or broken up any of the fittings of the school.

Assistance to Pregnant and Puerperal Women.

M. Paul Strauss has introduced into the Senate a Bill providing that no woman shall work for one month after her confinement. Compensation will be given to any woman duly recognised by law as being in this condition. M. Caillaux, the Minister of Finance, however, laid before the House some figures showing what would be the effect of the passage of this measure on the State and municipal budgets. The number of women who would profit under the law would be about 112,268. Supposing that the sum allowed were 1 franc per person per day the total sum would be 6,272,000 francs. At 1.50 francs the total expenses would be 9,408,000 francs. In the first case the contribution of the State would be 1,085,000 francs and in the second case 1,627,000 francs. The departmental and communal contributions would be much heavier—namely, in the first case 3,393,000 francs and in the second 5,089,000 francs. The Minister of Finance added that these figures required thinking over and, moreover, they only took into consideration the workers in towns. An amendment was put forward to include in the Bill every woman doing any remunerative work as soon as she arrives at the last period of her pregnancy. M. Caillaux refused to accept this amendment, which he said would entail an extra charge of 20 or 25 million francs on the Exchequer. The House then went on to consider a clause dealing with puerperal women, the object of the clause being to secure that every pregnant or puerperal woman for one month before, or one month after, her confinement should not be liable to have her contract of service broken on account of her condition. The Senate, however, agreed to the following altered form of the clause: "That no employer should break a woman's contract of service simply because she did not work during the month before or the month after her confinement."

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Operative Treatment in a case of Circumscribed Serous Meningitis.

IN the *Korrespondenzblatt für Schweizer Aerzte* of Nov. 1st Dr. C. de Montet publishes a remarkable case of paralysis where the symptoms were alleviated by surgical interference. He first referred to similar cases reported by Krause, Bruns, Sänger, V. Horsley, and especially Oppenheim, in a recent treatise on the diagnosis and treatment of tumours, and then went on to describe his case. The patient, an unmarried woman, aged 53 years, fell ill in December, 1907, with acute pain in the upper spinal region radiating into the pectoral regions. Pain and weakness followed and at last, in January, 1908, severe paresis of the legs ensued. The patient then entered the Thurgovian Cantonal Hospital at Münsterlingen. By Feb. 10th the condition was worse. The interscapular pains, though intermittent, were more intense and reached all round the thorax. The sphincter muscles of the bladder and rectum were paralysed. The pulse stood at 88 and the temperature varied from 98·5° to 100° F. There was almost complete paralysis of both legs. The reflexes were increased. Sensitiveness was decreased downward in an almost horizontal line at the level of the xiphoid process. The fourth and fifth vertebral spines were very sensitive to pressure. Puncture of the lumbar sac did not indicate any increase of lymphatic pressure. There were slight lymphocytosis and leucocytosis; the bacteriological examination was negative, and the antecedent history was uneventful. The diagnosis was difficult, but as the symptoms rapidly increased in severity and cystitis set in, Dr. Brunner, the house surgeon, performed an explorative laminectomy. This was on Feb. 25th. A great quantity of liquor cerebrospinalis escaped, evidently under high pressure, and the diagnosis of localised serous meningitis was made. The recovery was fairly rapid and complete. The patient left the hospital on March 30th. She was visited on May 18th and had resumed all her former occupations.

Sunshine and Longevity.

The official inquiry office of Magliaso in the canton of Tessin has published some interesting statistics relating to meteorological observations and their connexion with longevity. The meteorological observations all refer to the year 1906 and to several hundred villages and towns, and speak very favourably of the weather conditions in many places in very sheltered positions varying in altitude from 200 to 800 metres above sea level (700 to 2500 feet). In most of these simple but sufficient accommodation in small hotels and pensions has increased and multiplied. The observations show a maximum of at least 300 days with sunshine in many localities, Carabietta and Pentilino, near Lugano, heading the list with 327 and 331 sunny days respectively. Locarno and Lugano are also famous for their supply of sunshine but little need be said as these are well-known winter health resorts affording the best of accommodation for travellers in search of a mild and equable winter climate, but in March and April these places are liable to be overcrowded. How far the extraordinary amount of sunshine goes to promote longevity it is difficult to say, but the percentage of old people is exceptionally high in the canton of Tessin. The number of old people over 70 years of age in a population numbering 149,384 persons amounted to 6422, or 44 per 1000, 10 per 1000 being octogenarians. The corresponding numbers for the United Kingdom are, I believe, 27 per 1000 in England and Wales, 29 per 1000 in Scotland, and 42 per 1000 in Ireland It must be mentioned that a goodly number of inhabitants of the canton of Tessin emigrate and return after several decades to spend the rest of their lives in their simple country homes.

Zürich, Nov. 16th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

A New Clinic for Psychiatry at Budapest.

THE new clinic of the Budapest Royal University for the study of psychiatry was recently declared open by Count vicinity of the cells, namely, that of the lymphocytes existing in the lymph spaces, and there cannot be a doubt, in view of the known facts connected with these bodies, that they play a most important part in connexion with the synthetic reconstruction of the absorbed digestion products.

It is to be said of these lymphocytes that they are actively growing and proliferating bodies, particularly so when food is being absorbed. Kölliker, as far back as the middle of the last century, drew attention to the parenchyma of the villi being densely filled with them whilst digestion is going on, and remarked that, whilst never absent, they are, at other times, far fewer. It is only in connexion with the small intestinal part of the alimentary canal that this special development of lymphocytes is noticeable. Both in the case of the stomach and of the large intestine, a widely marked difference is observable, there being in these latter portions of the canal no more lymphocytes visible than may be seen in connexion with tissues generally.

A special lymphocyte growth, then, occurs in the villi in association with the absorption of the products of digestion from the intestinal canal. In my work on "Carbohydrate Metabolism and Diabetes," 1906, I entered fully into this subject in relation to the assimilation of carbohydrate by being embodied into protein, and gave photo-micrographic representations in illustration of the conditions observable. What was said in regard to carbohydrate equally applies to the nitrogenous part of the broken-down protein. They both disappear at the seat of absorption, and, accompanying their disappearance, there is an indisputable extensive

GENESIS OF PROTEIN THROUGH THE MEDIUM OF THE LYMPHOCYTE

formation that takes place.

With respect to mode of growth, lymphocytes may be looked upon as standing in the same position as unicellular organisms in a culture pabulum. The growth involves construction of protein out of surrounding more elementary principles. This constitutes an operation of universal occurrence in connexion with all living matter, seeing that protein is the constitutional basis of living matter, and that growth of living matter is attended with its formation. The construction of protein therefore runs concurrently with the growth of living matter, and, in the case of the intestinal lymphocytes, observation shows that the food-supply is at the foundation of their activity of growth.

Just as bacteria grow in a culture medium, so, it may be considered, do the intestinal lymphocytes grow upon the products of digestion that have passed by diffusion into the lymph spaces of villi. Anyone can satisfy himself of the influence exerted by food absorption on the state of the villi in relation to lymphocyte growth. If a rabbit, for instance, be killed at a period of full fasting, nothing is to be seen of lacteal vessels upon the intestine, and the receptaculum chyli even may not be susceptible of being discerned. The lacteal system seems to be in a state of quiescence, and to all appearances there cannot be any material flow of fluid taking place through the vessels. Killed at a period of full digestion, the contrast in appearance is very great. The lacteals are to be seen ramifying in a most conspicuous manner upon the surface of the intestine, the vessels that course through the mesentery stand out boldly as visible objects, and the receptaculum chyli is easily recognisable through the medium of its fluid contents. There cannot be the slightest question about an active flow of chyle taking place through the lacteal into the vascular system at a period of digestion, and if this is the case, does it not necessarily imply a corresponding transmission of protein, emanating from the food, into the blood?

The plasma of lymph and chyle is known to contain identically the same protein principles as the plasma of the blood. It is only in amount that a difference exists, and it is generally considered that the protein content of chyle plasma may be put down as being ordinarily equal to about half of that of the blood, or somewhere about 3·5 to 4 per cent., and that of lymph plasma to something less. I think it cannot be otherwise than conceded that the outflowing lymph and chyle derive their characters from within the absorbent system, and the lymphocytes may be regarded as constituting the source of the proteins met with. It is evident that these proteins cannot arise from self-production, but must be preceded by bioplasm, and be constructed by its synthesising agency. No other conclusion is permissible, and in the lymphocytes and their environment, the conditions exist for supplying what is wanted.

LYMPHOCYTE AUTOLYSIS

completes the process, and it may be reasonably concluded that this autolysis is not confined to lymphocytes that have entered the blood, but may also ensue antecedently to the blood being reached.

What I want to urge is that the reconstructed protein from the digestion products is formed at the seat of absorption and flows into the blood through the thoracic duct, instead of the digestion products being conveyed as such through the circulatory system to the tissues and there re-synthesised. It appears to me, if such a procedure as the latter actually occurred, it could not escape being revealed, as already insisted upon, alike in the case of carbohydrate and protein, by the state of the urine, upon the principle founded on observation that small molecular bodies, such as digestion products consist of, if permitted to reach the blood, find their way into the urine.

Under the view adopted, the blood is maintained in a renovated state by a supply of elaborated material thrown into it from the absorbent system, and derived in part from the food, and in part from the unutilised portion of the blood plasma which has escaped from the capillaries into the lymph spaces for the service of the tissues and subsequently become worked up by lymphocyte growth into the specific protein principles that flow into the blood.

With these circumstances confronting us, I do not see how the direct transmission of the digestion products from the food into the blood can be contended for, and the part played by the lacteal system in relation thereto, ignored. If anything at all approaching the quantity of chyle that is supposed to flow through the thoracic duct reaches the blood, the amount of protein passing with it must be something very considerable, and at the same time adequate to meet the required conditions belonging to tissue demand and food supply.

There are two forms in which protein passes into the blood—in the form of plasma protein, and in the form of lymphocytes. What is observed in connexion with

DIGESTION LYMPHOCYTOSIS

gives an idea of the extent of transmission of protein in the form of lymphocytes. Gulland, who has identified himself with the subject of blood counts, says that the lymphocytes show a continuous rise in number up to about the fourth or fifth hour after the ingestion of food, and that the total number per cubic millimetre of blood had often been found to be increased from 3000 up to 11,000 in the course of an hour. He also speaks of a fall in number being afterwards almost as rapid. I read the fall as constituting the result of autolysis, by the instrumentality of which the newly formed bioplasm becomes resolved into the protein constituents of the blood.

Cases have occurred in which, through injury to the thoracic duct, its contents have escaped, instead of flowing into the blood, and the effects observed have coincided with what might be looked for under the view that the nutrient supply from the food reaches the system in the manner contended for. A striking case of the kind is reported by Mr. R. T. H. Bucknall of University College Hospital, in the second volume of the *British Medical Journal* for 1905, p. 809. The patient was operated on for the removal of some tuberculous glands at the root of the neck. The thoracic duct was accidentally severed in the performance of the operation, without its being at first known that such had occurred. Instead of making favourable progress afterwards, great weakness, it is stated, was complained of, and, at the end of 24 hours, we are told the patient sank back in bed apparently very exhausted. It was then noticed that the dressing was soaked with a large quantity of clear yellowish fluid, and, on exploration, similar fluid was seen to be oozing rapidly from the wound. The wound was plugged, but the plugging proved of no avail, and from two to three pints of fluid leaked away every day, at times slowly, and at times more rapidly, clear and thin on the whole, but definitely chylous after meals. The patient, it is next said, lost strength in a remarkable manner and grew visibly thinner, so much so that it was obviously imperative to check any further leakage without delay. This was successfully accomplished by ligaturing the ends of the divided into the subject of malaria should be directed to investigate the question of drainage also. His inquiries should show what further drainage lines are desirable. The conference suggest no modifications in the methods adopted against plague which are the outcome of the years of experiment and experience. The result of the experiments now being made at Gorakhpur to render houses rat-proof should be awaited. The use of wire netting in the floors and walls of houses should prevent incursions by rats. A circular should also be issued recommending local authorities to encourage the keeping of cats. The question of the possibility of directly diminishing infant mortality has been considered. A note on the subject prepared by Major White, I.M.S., officiating sanitary commissioner, United Provinces, shows that the chief causes of the high mortality of infants in India are the immaturity and ignorance of mothers, improper feeding, and the exposure of infants to all the influences of an insanitary environment. Other causes are the want of skilled midwives, neglect of treatment of infantile diseases, disregard of primary rules of sanitation in the lying-in rooms, low nutritive value of food for mothers, poor clothing, and poor houses. An analysis of a table of infantile deaths submitted to the Calcutta municipality shows that convulsions, tentanus, and bronchitis carry off the largest proportion of infants. Tetanus is probably caused by the custom of rubbing dry earth or earth mixed with cow dung into the navel and careless exposure explains the large incidence of pulmonary diseases. The conference suggests that a certain number of women of the professional midwife classes should be trained for the purpose of serving as peripatetic *dais* under district boards. It considers that cheap maternity hospitals should be erected in the large towns, separate and distinct from the Dufferin hospitals. Such institutions would be under the charge of trained *dais* and be intended for the use of the poorer classes. The conference has before suggested that at least one model dairy should be established in each large town and has proposed additions to the Municipal Act giving boards greater control over cattle sheds and cow houses. It recommends that with a view to ascertaining more definitely the causes of infant mortality in these provinces a special inquiry should be conducted during one year in a typical town, preferably Cawnpore. The conference considers that in view of the popularity of Almora as a health resort by consumptives and the desirability of not only affording facilities for treatment to such persons, but also protecting Almora itself against infection, a hospital should be constructed outside the town to be used mainly by paying patients. Finally, the conference recognising that the main hope for improvement in the future lies in the education of the rising generation, recommends that sanitation and hygiene of an elementary character should be taught in all boys' and girls' schools up to the eighth class, and that the course should be compulsory up to that class and optional afterwards. Simple sanitary rules should be issued free or at a nominal price by district boards.

Punjabi Women and Vaccination.

To overcome the opposition of the women is one of the problems confronting the vaccination department of the Punjab. In many places, we are told, women still regard a visit to Mata Devi as a far more efficacious protection against small-pox than vaccination. During the last three years the number of primary vaccinations performed show a persistent annual decline, though the total for the three years is greater than the total for the previous triennium. The Lieutenant-Governor accepts plague and the consequent reductions in births as the explanation of this, though the fluctuations in the figures of particular districts are probably affected chiefly by the popularity and energy or the absence of these qualifications in the vaccinators. The fraction of the population which submits to revaccination is minute. The personal equation appears to enter largely into the calculations of the success of the operations, for while one Deputy Sanitary Commissioner found 61 per cent. of successes in revaccinations, the other found 99 per cent.; and similarly in the same districts the different inspecting officers record very different proportions of success. It can hardly be that the facts which came under the notice of the different officers differed so greatly as the statistics would imply, and it would seem that a more accurate definition of what is a successful revaccination is required. The Lieutenant-Governor is inclined to doubt whether the present very elaborate system of inspection of vaccinated persons by a supervising establishment is to be commended. The purpose of inspection is to see that the vaccinators do their work properly, and surely it is not necessary in order to secure this that babies should be bailed twice or possibly three times before an inspecting officer. It is probable that the trouble of these inspections and the long waits of the mothers with their children, even if there are no tiring tramps for them, do more to deter the women from producing their children for vaccination than the nuisance of the vaccination itself. The propriety of reducing the inspecting staff will be considered. The Vaccine Institute has worked well and the cost of vaccine is now 10 annas per gramme. The most important event in the history of the triennium has been the transfer at the beginning of this year of the vaccinating staff from the sanitary commissioner to the local bodies by which the staff is paid, a step which it is hoped will help to popularise vaccination.

Oct. 22nd.

Obituary.

PETER WILLIAMS, M.R.C.S. ENG., L.M., L.S.A.

THERE passed away at Ferryside on Oct. 29th, in the person of Mr. Peter Williams, aged 77 years, a member of a medical family who have practised in Carmarthenshire for nearly a hundred years. The son of Mr. E. Williams, surgeon, of Carmarthen, he was a pupil of his brother Dr. John Williams of the same town, who also had as a pupil Dr. Frederick T. Roberts. Entering St. Bartholomew's Hospital he became fully qualified in 1856. At first he joined his brother at Carmarthen, but in 1860 he started in practice at the seaside resort of Ferryside, Carmarthenshire. Here he worked for nearly 50 years and never was a medical man more beloved; rich and poor alike appreciated his services. His manner was so sympathetic and he took such infinite pains with his patients that he soon acquired a reputation which reached far beyond the bounds of Ferryside. About three years ago he practically retired in favour of his son, and was presented on the occasion with a cheque for £300 and a handsome piece of plate, this being the second testimonial which he received during his medical career. In April last he showed signs of serious organic heart trouble, and was then so ill that his life was despaired of, but he recovered to a certain extent; however, this was the beginning of the end, for on Oct. 29th he had another serious attack which ended fatally notwithstanding all the efforts of his son. His funeral was a public one and the whole neighbourhood was represented. There were representatives from public bodies at Carmarthen, Kidwelly, and Ferryside, also from the villages far and near. The body was carried to the old church of St. Ishmael's and was followed by a large concourse of people. Never has there been a more impressive funeral service in that church. It was by the wish of his widow entirely in Welsh. The church was full to overflowing and the evidences of grief were so profound that they testified to the great love which the people had for him. The chief mourners were Dr. Lewis Williams, Mr. Lloyd Williams, Mr. E. Williams, and Mr. H. Williams, sons; Dr. A. Glover Williams, nephew; the Rev. D. Morris, rector of Penally; the Rev. J. Rees, rector of Letterston; Lady Greaves; and the Rev. E. Rowlands. Amongst those attending the funeral was Sir John Williams, Bart., M.D., a personal friend of the deceased, who showed him many acts of kindness during his illness.

EDWARD WHISHAW HENLEY, L.R.C.P. LOND., M.R.C.S. ENG.,

MEDICAL SUPERINTENDENT OF THE GLOUCESTER COUNTY ASYLUMS.

Mr. E. W. Henley died in Gloucester on Nov. 14th, after an operation for appendicitis. He received his medical education at St. George's Hospital and qualified M.R.C.S. Eng. and L.R.C.P. Lond. in 1875 and 1876 respectively.

rise to the diverse manifestations of life that present themselves to our notice. That a linked-on group can affect and upset the proceedings within the molecular complex is shown by the effect produced when a toxin molecule is taken on.

In the natural course of events, the receptors or arms are designed for taking on nutrient molecules of various kinds, and amongst these, protein molecules are included. Upon this point Ehrlich, in his Royal Society Croonian lecture, says: "If a cell of the organism has, with the assistance of an appropriate 'side-chain,' fixed to itself a giant molecule, there is provided one of the conditions essential for the cell nourishment. Such giant molecules cannot at first be utilised by the cells, and are only made available when, by means of a ferment-like process, they are split into smaller fragments. This will be very effectually attained if, figuratively speaking, the 'tentacle' or grappling arm of the protoplasm possesses a second haptophore group adapted to take to itself ferment-like material out of the blood fluid."

What is here meant is that the receptor or side-chain is not only provided with an ending for taking on the protein nutrient molecule, but in addition, another ending constructed for taking on a particular molecular group to which the name of complement is assigned in the nomenclature adopted. This body is regarded as possessing ferment-like properties, and as existing in a free state in the blood serum, so as to be ready for anchorage wherever a suitable molecular group ending is to be found. It is supposed to stand in the same position towards the nutrient molecule as the lysin complement does to the red blood corpuscle, action occurring through the amboceptor which links both together; and, like the lysin complement, it loses its activity, as a ferment does, by exposure to a temperature of about 55° C.

To briefly recapitulate,

THE VIEW THAT HAS BEEN FORMULATED

may be thus summarised. Food that has been broken down and placed in a fit state by digestion for absorption is at once dealt with at the seat of absorption, and rebuilt into an elaborated form. Dextrose and peptone are alike recognisable at the seat of absorption, but both thereafter disappear. At the same time, and at the same spot, there is an active bioplasmic growth taking place, and bioplasm is known to feed upon dextrose and upon peptone. The lymphocytes, which constitute the growing material, can be followed from the villi into the absorbent vessels, and thence through the thoracic duct into the vascular system. Concurrently and harmoniously with what has been represented, from the absorbent system aspect of the question, to occur, observation upon the blood has shown that during the digestion period there is so large an accession of lymphocytes as to have given origin to the application of the term digestion lymphocytosis to it.

The next event in the life-history of the lymphocyte is lymphocytolysis. There can be no doubt that production and disappearance constitute a routine procedure, and there are good grounds for inferring that the disappearance is attended with a melting down, and transformation into the protein constituents of chyle and blood plasma, thus bringing these principles, which we are accustomed to view as tissue pabulum, into direct relation with the food, and placing them, in fact, in the position of elaborated food.

Looked at in this way, the tissues draw their nutrient supply from material elaborated from the digestion products at the seat of absorption, instead of the digestion products being conveyed as such through the circulatory system to the tissues, an event that, on account of their small molecular nature should but does not, make itself evident to us by running off with the urine. Under the view advocated, the mode of tissue nourishment is brought into parallelism with what occurs in the incubation of the egg, for here it is noticeable that the nutrient supply exists under the form of elaborated material of a similar nature to that belonging to the blood.

It is not permissible to assume that all the protein that is formed enters as a component of the tissues before being broken down. It is known that the

UNUTILISABLE NITROGEN PASSES OUT OF THE BODY IN THE FORM OF UREA,

and it is also known that the urea eliminated stands proportionate to the protein matter ingested, instead of to the energy produced in the tissues. This being the case, protein breaking down must occur, with separation of the non-utilisable from the utilisable portion, independently of what occurs in association with energy production. To enter the tissue simply for the purpose of being broken down and giving off its unutilisable nitrogenous portion is an unlikely mode of procedure. Whilst within the lymphocyte, however, the process may very consistently take place through the instrumentality of intracellular enzyme action, and this view of the matter harmonises with the fact that the period at which the increased elimination of urea shows itself after the taking of food, about corresponds with that of maximum activity of lymphocyte autolysis.

The great point emanating from what has preceded is that the products of digestion become assimilated at the seat of absorption. By this assimilation they become rebuilt, before reaching the circulation, into molecules of sufficient size to be precluded from flowing off with the urine in their passage through the kidney, in contra-distinction to what is known to occur with the digestion products themselves when circumstances exist to lead to their demonstrable presence in the blood. All experimental work affords testimony of sugar standing in the same position as salines and urea in relation to the property of passing off with the urine.

Impermeability of the kidney to sugar is, as I have before stated, a pure

FICTION RAISED UPON THE FALSE CONCEPTION

of healthy urine being free from sugar. Facts show that the urine, indeed, stands in very sensitive relationship to the blood with respect to sugar. The behaviour of Fehling's solution may be considered to be answerable for having led to the error that has existed. It is now well understood that, whilst Fehling's solution is a test of extreme delicacy for sugar when in a pure state, the constituents belonging to the urine mask the reaction when the sugar is present in urine in small quantities only. After a long and hard struggle, the existence of sugar in healthy urine has come to be admitted, but a disposition to minimise its significance to the utmost possible extent is still noticeable.

The misconception that has so long prevailed has operated as a misguiding factor in connexion with the fundamental idea belonging to the glycogenic theory that the carbohydrate of our food is destined to pass through the circulatory system to the tissues in the form of sugar. In Michael Foster's textbook on "Physiology," at p. 613, we find it stated: "Now, a small amount of sugar is normally present in the blood, and *so long as this normal amount is not exceeded no sugar appears in the urine* [the italics are mine]. If, however, by some reason or other, the sugar in the blood is increased beyond that normal amount, the excess passes unchanged into the urine. And, the excess in the blood which thus leads to the excretion of unchanged sugar, is so small that we might expect it to be oxidised in the blood did the blood possess any considerable oxidising power." The identity of the idea here expressed with that expressed in the quotation from the author of the article in Hill's "Recent Advances in Physiology and Biochemistry" given in Lecture I., shows how deeply the groundless idea has become rooted in the minds of physiologists.

The misleading nature, upon a vital point, of such a conception cannot be otherwise than obvious to everyone. It implies, contrary to fact, that sugar may reach the blood of the general circulation without its presence being revealed by the urine. The real circumstances are that the urine constitutes an indicator of the state of the blood with respect to sugar, no matter whether the amount existing be large or small, and thence it may be concluded that if sugar were reaching the circulation, as is contended for under the glycogenic theory, it could not escape being rendered evident by the urine, just as indeed happens in connexion with diabetes.

THE WARR MEMORIAL AT THE LIVERPOOL ROYAL INFIRMARY.—The committee in charge of the fund raised as a memorial to the late Mr. Augustus F. Warr (formerly M.P. for one of the Liverpool divisions, and a member of the committee of the Liverpool Royal Infirmary) has announced that the sum of £4650 has been subscribed. Out of this amount the sum of £500 is to be offered to the committee of the Royal Infirmary towards the endowment of a bed to be associated permanently with Mr. Warr's name.

M.B., Ch.B. Edinburgh, Edinburgh University; Josiah Walker, B.A. Cantab., Cambridge University and Guy's Hospital; Harold Eustace McMahon Wall, St. Mary's Hospital; George Henry Hitchcock Waylen, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Arthur Leonard Weakley, St. Bartholomew's Hospital; Walter Weir, St. Thomas's Hospital; Ambrose Cyril Wilson, St. Bartholomew's Hospital; Ernest William Witney, St. Thomas's Hospital; Charles Albert Wood, Guy's Hospital; Wilfrid Burton Wood, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; and Albert Edward Mortimer Woolf, B.A. Cantab., Cambridge University and London Hospital.

* M.R.C.S. diploma granted on Oct. 15th last.

† M.R.C.S. diploma granted under regulations previous to 1884.

Royal College of Surgeons of England.—At the Primary Examination in Anatomy and Physiology for the Diploma of Fellow, held on Nov. 5th, 6th, 10th, 11th, and 12th, 97 candidates presented themselves, of whom 38 per cent. passed and 62 per cent. were rejected. The following are the names of the successful candidates:—

William Bradshaw Ainger, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Henry Graeme Anderson, M.B., Ch.B. Glasg., Glasgow University and King's College Hospital; John Bruce Baird, B.Sc., Otago and Glasgow Universities; Dinsha Darasha Baria, L.M. & S. Bombay, L.R.C.P., M.R.C.S., Bombay University and King's College; Phiroz Byramji Bharucha, L.M. & S. Bombay, Bombay and King's College; Aleck William Bourne, B.A. Cantab., Cambridge University and St. Mary's Hospital; Frank Cook, Guy's Hospital; Ellis Patrick Crozier, Ceylon Medical College and London Hospital; Kenneth James Acton Davis, B.A. Cantab., Cambridge University and King's College; William Square Edmond, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Hugh Arthur Evans, King's College and Westminster Hospital; Rupert Farrant, L.R.C.P., M.R.C.S., Westminster Hospital and King's College; Edward Cecil Foster, L.R.C.P., M.R.C.S., University College Hospital; Arthur Duncan Gardner, B.A. Oxon., Oxford University and St. Thomas's Hospital; Harold Delf Gillies, B.A. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Richard Henry Cyril Gompertz, M.B., B.S. Lond., L.R.C.P., M.R.C.S., King's College Hospital; Harold Kinder Griffith, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; David Colvin Henry, M.B., Ch.B. Edin., Edinburgh University and St. Bartholomew's Hospital; Charles Henry James, Major I.M.S., L.R.C.P., M.R.C.S., St. Thomas's and King's College Hospitals; Rupert Llewellyn Jones, London Hospital; Harold Albert Kisch, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Thomas's Hospital; William Hugh Leonard, Captain I.M.S., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital and King's College; Norman Francis Lock, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Henry Linnington Martyn, King's College; James Menzies, St. Mary's Hospital; Thomas Bernard Mouat, M.B., Ch.B. Edin., Edinburgh University; William Fulton Neil, M.B., Ch.B. New Zealand, L.R.C.P., M.R.C.S., New Zealand University and Middlesex Hospital; Robert Ollerenshaw, M.D., B.Ch. Vict., L.R.C.P., M.R.C.S., Victoria University, Manchester; John Francis O'Malley, L.R.C.P. & S.I., L.M. Dub., King's College and Middlesex Hospitals; Hugh Raymond Guy Poate, M.B., Ch.M. Sydney, L.R.C.P., M.R.C.S., Sydney University, University College, and Middlesex Hospitals; Alfred Henry Richardson, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Richard Alun Rowlands, B.Sc. Wales, London Hospital; Frederic Sanders, London Hospital; Hew William Scott-Wilson, Oxford University; Harry Bertram Walker, London Hospital; Clifford Sidney White, M.D., B.S. Lond., L.R.C.P., M.R.C.S., University College Hospital; and William Stanley Wildman, London Hospital.

At the First Professional Examination for the Licence in Dental Surgery just completed the following gentlemen were approved in the subjects indicated below:—

Mechanical Dentistry and Dental Metallurgy.—Ernest Beddoes, Liverpool University; Sydney Martin Bell, Royal Dental Hospital; Samuel Isaac Blairman, Royal Dental Hospital; Cecil Lucas Donne, National Dental Hospital; William Kelsey Fry, Guy's Hospital; Stanley Maddox Gardner, Royal Dental Hospital; Frederick Simpson Glover, Guy's Hospital; Leslie Price Harris, Guy's Hospital; Laurence Edgar Crespin Harrison, National Dental Hospital; Edward Palmer Hudson, Guy's Hospital; William Edward Jones, Liverpool University; Leslie Gordon Kinnersley, University College, Bristol; John Knowles, Royal Dental Hospital; Harold William Knowling, Liverpool University; Edward Aubrey Clement Knox-Davies, Guy's Hospital; Harris Raphael Lyons, Royal Dental Hospital; Rupert Mallinson, Royal Dental Hospital; Benjamin Henry Masselink, D.M.D. Michigan, Michigan University; Leslie Miller, Royal Dental Hospital; Wilfred Woolfe Miron, National Dental Hospital; Arthur Stanley Morgan, Guy's Hospital; Victor Mayfield Morris, National Dental Hospital; Percy Hills Orton, Guy's Hospital; John Hayward Paget, Royal Dental Hospital; Frederick William Paul, Guy's Hospital; George Evan Henry Holt Phillips, Guy's Hospital; Alfred Graham Poock, B.A. Cantab., Guy's Hospital; William Macqueen Potter, Royal Dental Hospital; Reginald Wood Powell, Guy's Hospital; George Brentnall Pritchard, Guy's Hospital; Wilfrid Aubrey Rowe, Royal Dental Hospital; Charles Frederic Leyson Ruck, Guy's Hospital; Bernard Edward Patrick Sayers, Royal Dental Hospital; Charles Foote Snow, Guy's Hospital; Claud Stacey, National Dental Hospital; Gordon Bower Sutton, Royal Dental Hospital; Robert Douglas Breen Turner, Liverpool University; and Thomas Edwin Wills Royal Dental Hospital.

Mechanical Dentistry.—Robert Dudley Bell, Royal Dental Hospital; Rowland Burnell Campion, Guy's Hospital; Gordon Comyn, Royal Dental Hospital; Charles Repton Faulkner, Birmingham University; Robert Daniel Gregg, Liverpool University; Harold Harrison, Guy's Hospital; Kenneth George Hoby, Guy's Hospital; William Lowe Jackson, Royal Dental Hospital; Henry Kinnear Ovey, Royal Dental Hospital; Ronald Victor Payton, Birmingham University; Archie Ernest Frederick Peaty, Guy's Hospital; Harold Ernest Pow, Royal Dental Hospital; George Henry Rowley, Guy's Hospital; Alfred Edmund Victor Spill, Guy's Hospital; Edward Algernon Weaver, Birmingham University; Charles Eustace Williams, Royal Dental Hospital; William Hector Wotton, Guy's Hospital; Edgar Olyve Yerbury, Guy's Hospital; and Henry Stanley Young, Royal Dental Hospital.

Dental Metallurgy.—Cecil William Bond, L.R.C.P., M.R.C.S., Royal Dental Hospital; Harold Edgar Bower, Royal Dental Hospital; Ralph Chapman, Royal Dental Hospital; George Vivian Dymott, Guy's Hospital; Niel Edgar, Guy's Hospital; John Eric Rhys Evans, Guy's Hospital; Edwin Llewellyn Zenas Fickling, Royal Dental Hospital; Victor William Russell Forbes, Royal Dental Hospital; Lawrance Richards Haydon, Royal Dental Hospital; Frank James Hayman, University College, Bristol; Frederic Amos Jaques, Guy's Hospital; Arthur Percy Livett Johnson, Guy's Hospital; George Bertrand Lucas, Royal Dental Hospital; Leonard Clive Matthews, Birmingham University; John Dudley Melhuish, University College, Bristol; Owen Colville Morphy, Royal Dental Hospital; Cyril Arthur Pollard, Guy's Hospital; Gordon Evelyn Rowstron, Guy's Hospital; Frank Percival Sturdee, Royal Dental Hospital; John Herbert Wiles, Guy's Hospital; and Frederic Charles Willows, University College, Bristol.

University of Cambridge.—The following degrees were conferred on Nov. 12th:—

M.D.—F. D. Nicholson, King's.
M.B., B.C.—R. L. Gamlen and C. H. T. Ilott, Caius.

The General Board of Studies will shortly proceed to the election of a University lecturer in zoology at an annual stipend of £50. Applications should be made to the Vice-Chancellor before Dec. 2nd.

Royal College of Surgeons in Ireland: Dental Examination.—The following candidates having passed the necessary examination have been admitted Licentiates in Dental Surgery:—

A. J. Adkins, M.R.C.S. Eng., G. C. Bull, M.R.C.S. Eng., J. V. M. Byrne, R. G. Fitchie, J. R. Hackett, M.B., B.Ch. R.U.I., H. J. Hedley, A. E. J. Moore, D. McC. Smith, and L. P. Vernon.

The following candidates have passed the primary part of the Dental Examination:—

J. J. Lyons and R. T. Mosbery.

Foreign University Intelligence.—*Berlin* (*Kaiser Wilhelm's Military Medical Academy*): Surgeon-General Eduard Pfuhl, Principal of the Laboratory of Chemistry and Hygiene, has resigned.—*Dresden*: Dr. Lindner, of the Dresden-Friedrichstadt Hospital, formerly Principal of the Surgical Department of the Augusta Hospital, Berlin, has been granted the title of Professor by the Grand Duke of Mecklenburg-Strelitz.—*Leipsic*: Dr. Rolly, *privat-docent* of Medicine, has been granted the title of Extraordinary Professor.—*Rostock*: Dr. Ernst Franke has been recognised as *privat-docent* of Surgery.—*Strasburg*: Dr. Rosenfeld, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Utrecht*: Dr. Steensma has been appointed Lecturer on Chemical Diagnosis.—*Würzburg*: Two new Extraordinary Professorships have been established: one of Laryngology to which Dr. Seifert has been appointed, the other of Odontology which has been assigned to Dr. Michel.

The Brompton Hospital for Consumption and Diseases of the Chest.—The following lectures and demonstrations have been arranged to be delivered throughout the winter session, 1908–09, on Wednesdays, at 4 P.M.:—Nov. 25th, Dr. R. Maguire, Certain Heart Cases; Dec. 2nd, Dr. P. Horton-Smith Hartley, Pneumothorax; Dec. 9th, Dr. Hector Mackenzie, Cases from the Wards; Dec. 16th, Dr. R. A. Young, The Cardio-Vascular System in Cases of Pulmonary Tuberculosis; Jan. 13th, 1909, Mr. Stanley Boyd, Difficult Empyemata; Jan. 20th, Dr. Batty Shaw, Occult Cardiac Hypertrophy; Jan. 27th, Dr. S. H. Habershon, Cases from the Wards; Feb. 3rd, Dr. J. J. Perkins, Bronchiectasis; Feb. 10th, Dr. W. C. Bosanquet, Mediastinal Tumours. The course is free to all qualified medical practitioners and to students of medicine. It was inaugurated on Wednesday last, Nov. 18th, by Sir Richard Douglas Powell, consulting physician to the hospital, who delivered an address on Angina Pectoris.

The Medical Inspection of School Children.—A final course of lectures and demonstrations on the medical inspection of school children will be given by Dr. James Kerr, the chief medical officer of the Education Department of the London County Council, on Jan. 11th, 12th, 13th, and 14th, 1909. The lectures will be delivered in the rooms of the Society of Medical Officers of Health and the demonstrations will take place in the special schools of the London County Council. The course will also include lectures by Dr.

rise to the diverse manifestations of life that present themselves to our notice. That a linked-on group can affect and upset the proceedings within the molecular complex is shown by the effect produced when a toxin molecule is taken on.

In the natural course of events, the receptors or arms are designed for taking on nutrient molecules of various kinds, and amongst these, protein molecules are included. Upon this point Ehrlich, in his Royal Society Croonian lecture, says: "If a cell of the organism has, with the assistance of an appropriate 'side-chain,' fixed to itself a giant molecule, there is provided one of the conditions essential for the cell nourishment. Such giant molecules cannot at first be utilised by the cells, and are only made available when, by means of a ferment-like process, they are split into smaller fragments. This will be very effectually attained if, figuratively speaking, the 'tentacle' or grappling arm of the protoplasm possesses a second haptophore group adapted to take to itself ferment-like material out of the blood fluid."

What is here meant is that the receptor or side-chain is not only provided with an ending for taking on the protein nutrient molecule, but in addition, another ending constructed for taking on a particular molecular group to which the name of complement is assigned in the nomenclature adopted. This body is regarded as possessing ferment-like properties, and as existing in a free state in the blood serum, so as to be ready for anchorage wherever a suitable molecular group ending is to be found. It is supposed to stand in the same position towards the nutrient molecule as the lysin complement does to the red blood corpuscle, action occurring through the amboceptor which links both together; and, like the lysin complement, it loses its activity, as a ferment does, by exposure to a temperature of about 55° C.

To briefly recapitulate,

THE VIEW THAT HAS BEEN FORMULATED

may be thus summarised. Food that has been broken down and placed in a fit state by digestion for absorption is at once dealt with at the seat of absorption, and rebuilt into an elaborated form. Dextrose and peptone are alike recognisable at the seat of absorption, but both thereafter disappear. At the same time, and at the same spot, there is an active bioplasmic growth taking place, and bioplasm is known to feed upon dextrose and upon peptone. The lymphocytes, which constitute the growing material, can be followed from the villi into the absorbent vessels, and thence through the thoracic duct into the vascular system. Concurrently and harmoniously with what has been represented, from the absorbent system aspect of the question, to occur, observation upon the blood has shown that during the digestion period there is so large an accession of lymphocytes as to have given origin to the application of the term digestion lymphocytosis to it.

The next event in the life-history of the lymphocyte is lymphocytolysis. There can be no doubt that production and disappearance constitute a routine procedure, and there are good grounds for inferring that the disappearance is attended with a melting down, and transformation into the protein constituents of chyle and blood plasma, thus bringing these principles, which we are accustomed to view as tissue pabulum, into direct relation with the food, and placing them, in fact, in the position of elaborated food.

Looked at in this way, the tissues draw their nutrient supply from material elaborated from the digestion products at the seat of absorption, instead of the digestion products being conveyed as such through the circulatory system to the tissues, an event that, on account of their small molecular nature should but does not, make itself evident to us by running off with the urine. Under the view advocated, the mode of tissue nourishment is brought into parallelism with what occurs in the incubation of the egg, for here it is noticeable that the nutrient supply exists under the form of elaborated material of a similar nature to that belonging to the blood.

It is not permissible to assume that all the protein that is formed enters as a component of the tissues before being broken down. It is known that the

UNUTILISABLE NITROGEN PASSES OUT OF THE BODY IN THE FORM OF UREA,

and it is also known that the urea eliminated stands proportionate to the protein matter ingested, instead of to the energy produced in the tissues. This being the case, protein breaking down must occur, with separation of the non-utilisable from the utilisable portion, independently of what occurs in association with energy production. To enter the tissue simply for the purpose of being broken down and giving off its unutilisable nitrogenous portion is an unlikely mode of procedure. Whilst within the lymphocyte, however, the process may very consistently take place through the instrumentality of intracellular enzyme action, and this view of the matter harmonises with the fact that the period at which the increased elimination of urea shows itself after the taking of food, about corresponds with that of maximum activity of lymphocyte autolysis.

The great point emanating from what has preceded is that the products of digestion become assimilated at the seat of absorption. By this assimilation they become rebuilt, before reaching the circulation, into molecules of sufficient size to be precluded from flowing off with the urine in their passage through the kidney, in contra-distinction to what is known to occur with the digestion products themselves when circumstances exist to lead to their demonstrable presence in the blood. All experimental work affords testimony of sugar standing in the same position as salines and urea in relation to the property of passing off with the urine.

Impermeability of the kidney to sugar is, as I have before stated, a pure

FICTION RAISED UPON THE FALSE CONCEPTION

of healthy urine being free from sugar. Facts show that the urine, indeed, stands in very sensitive relationship to the blood with respect to sugar. The behaviour of Fehling's solution may be considered to be answerable for having led to the error that has existed. It is now well understood that, whilst Fehling's solution is a test of extreme delicacy for sugar when in a pure state, the constituents belonging to the urine mask the reaction when the sugar is present in urine in small quantities only. After a long and hard struggle, the existence of sugar in healthy urine has come to be admitted, but a disposition to minimise its significance to the utmost possible extent is still noticeable.

The misconception that has so long prevailed has operated as a misguiding factor in connexion with the fundamental idea belonging to the glycogenic theory that the carbohydrate of our food is destined to pass through the circulatory system to the tissues in the form of sugar. In Michael Foster's textbook on "Physiology," at p. 613, we find it stated: "Now, a small amount of sugar is normally present in the blood, and *so long as this normal amount is not exceeded no sugar appears in the urine* [the italics are mine]. If, however, by some reason or other, the sugar in the blood is increased beyond that normal amount, the excess passes unchanged into the urine. And, the excess in the blood which thus leads to the excretion of unchanged sugar, is so small that we might expect it to be oxidised in the blood did the blood possess any considerable oxidising power." The identity of the idea here expressed with that expressed in the quotation from the author of the article in Hill's "Recent Advances in Physiology and Biochemistry" given in Lecture I., shows how deeply the groundless idea has become rooted in the minds of physiologists.

The misleading nature, upon a vital point, of such a conception cannot be otherwise than obvious to everyone. It implies, contrary to fact, that sugar may reach the blood of the general circulation without its presence being revealed by the urine. The real circumstances are that the urine constitutes an indicator of the state of the blood with respect to sugar, no matter whether the amount existing be large or small, and thence it may be concluded that if sugar were reaching the circulation, as is contended for under the glycogenic theory, it could not escape being rendered evident by the urine, just as indeed happens in connexion with diabetes.

THE WARR MEMORIAL AT THE LIVERPOOL ROYAL INFIRMARY.—The committee in charge of the fund raised as a memorial to the late Mr. Augustus F. Warr (formerly M.P. for one of the Liverpool divisions, and a member of the committee of the Liverpool Royal Infirmary) has announced that the sum of £4650 has been subscribed. Out of this amount the sum of £500 is to be offered to the committee of the Royal Infirmary towards the endowment of a bed to be associated permanently with Mr. Warr's name.

formation of the Central Midwives Board that this appeared be a case in which it was the duty of the Board to bring e facts under the notice of the Public Prosecutor. The oard decided that the facts in the case were to be laid efore the Public Prosecutor. Reports made at the request of e Board by various local supervising authorities as to the onduct of certain midwives previously censured or cautioned r offences against the rules were received and were of a enerally favourable character. 34 midwives were ordered be cited to attend a special penal meeting of the Board be held on Dec. 3rd to answer the charges alleged against hem by their respective local supervising authorities.

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—uring the summer a deputation, formed by the honorary ecretary, Dr. A. G. Haydon, from this association had an nterview with Professor Rommelaere, the rector of the niversity of Brussels. We are informed that on the epresentations of the Brussels Medical Graduates' Association the following concessions were promised to candidates or the M.D. degree:—

1. That it should be sufficient for English candidates to produce their ertificates of registration instead of their diplomas on presenting hemselves for examination at Brussels.
2. That the attention of the Administrative Council of the University hould be drawn to the insufficiency of certain Indian and American ualifications which do not entitle their holders to the full privileges f practice in their own country.
3. That the examination for the M.D. degree in February should in uture take place in March, this month being more convenient for nglish candidates.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Children Bill.

THE Children Bill passed through its report stage in the House of Lords on Thursday, Nov. 12th, but only slight alterations were made in the text of the measure.

The Housing and Town Planning Bill.

Mr. BURNS, the President of the Local Government Board, on Nov. 17th refused to accede to a request made by a Member of the Standing Committee of the House of Commons charged with the consideration of this Bill to drop the part of it relating to town planning. The motive of the request is a fear that if much longer time is spent upon the measure in committee its chances of becoming law this year will be shattered. Mr. BURNS expressed himself as sanguine of being able to carry the whole Bill, but his optimism is not shared by a number of the Members of the Committee.

Industrial Diseases.

The Departmental Committee on Compensation for Industrial Diseases has made a report on glass-worker's cataract and telegraphist's cramp. The Committee recommends that "cataract in glass-workers" should be added to the first column of the schedule of industrial diseases for which compensation may be claimed, and that "processes in the manufacture of glass involving exposure to the glare of molten glass" be added to the second column, but it is added that compensation should be made payable only in cases where an operation is undergone and for a period not exceeding six months. With regard to telegraphist's cramp, the Committee recommends that the application of Section 8 of the Workmen's Compensation Act, 1906, should be modified where the "workman" suffering from the disease is in the employment of the Postmaster-General by the substitution of the postal medical officer of the district for the certifying surgeon appointed under the Factory and Workshop Act, 1901, as the person by whom, in the first instance, the presence of the disease should be certified.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 11TH.

Lunacy and Marriage.

Captain FABER asked the Secretary of State for the Home Department whether, looking at the increase of lunacy, he could see his way to recommending that a Bill should be brought in to prevent the marriages of those persons who had ever been confined in a lunatic asylum.—Mr. GLADSTONE answered: No, Sir, it would be impossible to prohibit the marriage of all persons who have ever been confined in a lunatic asylum, because in many cases the mental trouble has been of a limited or temporary nature. The recommendations on the subject in the report of the Royal Commission on the Feeble Minded will be considered.

The Medical Department of Trinidad.

Mr. SUMMERBELL asked the Under Secretary of State for the Colonies whether his attention had been called to the administration of the medical department of Trinidad; and, if so, whether he could state it was the intention of the Government to take steps having for their object the reorganisation of that department on lines that would give to Trinidad a health ordinance on more modern lines.—Colonel SEELY said in reply: The Secretary of State has received no official representations on the subject and he is not aware that any scheme of reorganisation is under the consideration of the Colonial Government.

Tuberculosis in the Army.

Mr. SUMMERBELL asked the Prime Minister, in view of the promotion by the Government of the Tuberculosis Prevention (Ireland) Bill, to state whether it was the intention of the Government to adopt the recommendations of the Select Committee as to tuberculosis amongst soldiers, about 350 of whom were discharged every year suffering from this disease, and in regard to whom no provision for treatment was made by the State.—Mr. ASQUITH replied: I can add nothing to the statements already made by my right honourable friend the Secretary of State for War with regard to this matter. As has been stated, the Government is not prepared to adopt the recommendations of the Departmental Committee which inquired into this subject.

Public Health in Ramsey.

Mr. BOULTON asked the President of the Local Government Board whether he had seen the report *re* the prevalence of infectious disease and sanitary conditions existing in the urban district of Ramsey by the consulting medical officer of health; whether he was aware that the report stated that there was no water in the town fit for drinking; that the sewage of the town found its way, illegally, directly into the river; that the sanitary conveniences were insanitary and objectionable; whether he would take steps, for the protection of the inhabitants, to see that the urban district council put into force the powers it possessed under the Public Health Act; and what other steps he proposed to take to secure wholesome water and proper drainage for the town.—Mr. BURNS repied: I have obtained copies of the report made by the consulting medical officer of health to the Huntingdonshire county council on this subject, and I find that the report is generally to the effect mentioned in the question. The county council is in communication with the urban district council with respect to the steps to be taken in consequence of the recommendations made in the report, and the latter body was to hold a special meeting to consider the matter. I have requested that I may be informed of the action which the district council proposes to take with regard to it.

The Tuberculosis Prevention (Ireland) Bill.

Mr. GINNELL asked the Chief Secretary to the Lord Lieutenant of Ireland, seeing that no body of ratepayers had asked for the enactment of the Tuberculosis Prevention (Ireland) Bill, while all classes in Ireland desired the enactment of an adequate Land Bill, and that persisting so late in the session with one might endanger the other, whether he would consider the advisability of dropping the Tuberculosis Bill in favour of the promised Land Bill.—Mr. BIRRELL wrote in reply: I have received many resolutions from local authorities and other representative bodies in favour of the Tuberculosis Prevention Bill. It is not proposed to drop the Bill.

THURSDAY, NOV. 12TH.

The Local Government Board for Scotland.

Mr. WATT asked the Secretary for Scotland whether, in view of the increase to be presently effected in the staffing and *personnel* of the Local Government Board for Scotland, he would undertake that a veterinary surgeon with practical experience in meat inspection would be appointed to that Board in order to unify the standard of meat inspection throughout Scotland.—Mr. SINCLAIR furnished the following written answer: I can only inform my honourable friend that if and when an increase of staff of the Local Government Board is necessary all the representations that have been made will have due consideration.

The Transmission of Anthrax.

Mr. BRIGG asked the Secretary of State for Foreign Affairs whether he would give instructions to the consuls in the ports from which goats' hair, mohair, and low quality of wools were exported to circulate amongst the farmers, dealers, and packers in their respective districts a request that they would use every possible precaution to prevent blood stains and pieces of skin being sent to this country in bales for manufacturing purposes, as according to the recent discovery by Dr. F. W. Eurich of Bradford that the germs of anthrax were traceable to blood stains and not to the ordinary dust arising from the sorting of foreign materials, the fatal cases arising from anthrax might be diminished, and the costly regulations for dealing with ordinary dust might, if thought advisable, be considerably modified.—Sir EDWARD GREY (by written answer) replied: I am advised by the Secretary of State for the Home Department that the issue of such a request as is suggested in the question might possibly prove useful, though too great expectations must not be based upon it, and that, after consultation with the Home Office, steps will be taken to bring the suggestion to the notice of those interested.

Police Ambulances in the Metropolis.

Mr. COOPER asked the Secretary of State for the Home Department what was the total number of police wheeled-litter ambulances in the metropolitan area in each year from 1891 to 1907; and the total number at the present time.—Mr. GLADSTONE furnished the following written answer: The earlier figures cannot readily be given, but it may be assumed that previous to 1903 there was an ambulance at every police station. The total number of police ambulances on Dec. 31st of the undermentioned years was—1903, 190; 1904, 192; 1905, 193; 1906, 203; 1907, 263; and Oct. 31st, 1908, 278.

MONDAY, NOV. 16TH.

The Medicine Chest of the House of Commons.

Mr. PATRICK O'BRIEN asked the First Commissioner of Works [illegible] ements he had [illegible] y medical and [illegible] o apply them, [illegible] the House.— [illegible] ith every drug and instrument which the ingenuity or necessities of man can require has been generously presented to the House by a well-known firm of manufacturing chemists, who do not desire their name to be mentioned in the matter, but I am glad to take this opportunity of conveying to the anonymous donors the gratitude of those who may subsequently profit by these appliances. The contents of this chest were decided upon after the careful consideration and advice

rise to the diverse manifestations of life that present themselves to our notice. That a linked-on group can affect and upset the proceedings within the molecular complex is shown by the effect produced when a toxin molecule is taken on.

In the natural course of events, the receptors or arms are designed for taking on nutrient molecules of various kinds, and amongst these, protein molecules are included. Upon this point Ehrlich, in his Royal Society Croonian lecture, says: "If a cell of the organism has, with the assistance of an appropriate 'side-chain,' fixed to itself a giant molecule, there is provided one of the conditions essential for the cell nourishment. Such giant molecules cannot at first be utilised by the cells, and are only made available when, by means of a ferment-like process, they are split into smaller fragments. This will be very effectually attained if, figuratively speaking, the 'tentacle' or grappling arm of the protoplasm possesses a second haptophore group adapted to take to itself ferment-like material out of the blood fluid."

What is here meant is that the receptor or side-chain is not only provided with an ending for taking on the protein nutrient molecule, but in addition, another ending constructed for taking on a particular molecular group to which the name of complement is assigned in the nomenclature adopted. This body is regarded as possessing ferment-like properties, and as existing in a free state in the blood serum, so as to be ready for anchorage wherever a suitable molecular group ending is to be found. It is supposed to stand in the same position towards the nutrient molecule as the lysin complement does to the red blood corpuscle, action occurring through the amboceptor which links both together; and, like the lysin complement, it loses its activity, as a ferment does, by exposure to a temperature of about 55° C.

To briefly recapitulate,

THE VIEW THAT HAS BEEN FORMULATED

may be thus summarised. Food that has been broken down and placed in a fit state by digestion for absorption is at once dealt with at the seat of absorption, and rebuilt into an elaborated form. Dextrose and peptone are alike recognisable at the seat of absorption, but both thereafter disappear. At the same time, and at the same spot, there is an active bioplasmic growth taking place, and bioplasm is known to feed upon dextrose and upon peptone. The lymphocytes, which constitute the growing material, can be followed from the villi into the absorbent vessels, and thence through the thoracic duct into the vascular system. Concurrently and harmoniously with what has been represented, from the absorbent system aspect of the question, to occur, observation upon the blood has shown that during the digestion period there is so large an accession of lymphocytes as to have given origin to the application of the term digestion lymphocytosis to it.

The next event in the life-history of the lymphocyte is lymphocytolysis. There can be no doubt that production and disappearance constitute a routine procedure, and there are good grounds for inferring that the disappearance is attended with a melting down, and transformation into the protein constituents of chyle and blood plasma, thus bringing these principles, which we are accustomed to view as tissue pabulum, into direct relation with the food, and placing them, in fact, in the position of elaborated food.

Looked at in this way, the tissues draw their nutrient supply from material elaborated from the digestion products at the seat of absorption, instead of the digestion products being conveyed as such through the circulatory system to the tissues, an event that, on account of their small molecular nature should but does not, make itself evident to us by running off with the urine. Under the view advocated, the mode of tissue nourishment is brought into parallelism with what occurs in the incubation of the egg, for here it is noticeable that the nutrient supply exists under the form of elaborated material of a similar nature to that belonging to the blood.

It is not permissible to assume that all the protein that is formed enters as a component of the tissues before being broken down. It is known that the

UNUTILISABLE NITROGEN PASSES OUT OF THE BODY IN THE FORM OF UREA,

and it is also known that the urea eliminated stands proportionate to the protein matter ingested, instead of to the energy produced in the tissues. This being the case, protein breaking down must occur, with separation of the non-utilisable from the utilisable portion, independently of what occurs in association with energy production. To enter the tissue simply for the purpose of being broken down and giving off its unutilisable nitrogenous portion is an unlikely mode of procedure. Whilst within the lymphocyte, however, the process may very consistently take place through the instrumentality of intracellular enzyme action, and this view of the matter harmonises with the fact that the period at which the increased elimination of urea shows itself after the taking of food, about corresponds with that of maximum activity of lymphocyte autolysis.

The great point emanating from what has preceded is that the products of digestion become assimilated at the seat of absorption. By this assimilation they become rebuilt, before reaching the circulation, into molecules of sufficient size to be precluded from flowing off with the urine in their passage through the kidney, in contra-distinction to what is known to occur with the digestion products themselves when circumstances exist to lead to their demonstrable presence in the blood. All experimental work affords testimony of sugar standing in the same position as salines and urea in relation to the property of passing off with the urine.

Impermeability of the kidney to sugar is, as I have before stated, a pure

FICTION RAISED UPON THE FALSE CONCEPTION

of healthy urine being free from sugar. Facts show that the urine, indeed, stands in very sensitive relationship to the blood with respect to sugar. The behaviour of Fehling's solution may be considered to be answerable for having led to the error that has existed. It is now well understood that, whilst Fehling's solution is a test of extreme delicacy for sugar when in a pure state, the constituents belonging to the urine mask the reaction when the sugar is present in urine in small quantities only. After a long and hard struggle, the existence of sugar in healthy urine has come to be admitted, but a disposition to minimise its significance to the utmost possible extent is still noticeable.

The misconception that has so long prevailed has operated as a misguiding factor in connexion with the fundamental idea belonging to the glycogenic theory that the carbohydrate of our food is destined to pass through the circulatory system to the tissues in the form of sugar. In Michael Foster's textbook on "Physiology," at p. 613, we find it stated: "Now, a small amount of sugar is normally present in the blood, and *so long as this normal amount is not exceeded no sugar appears in the urine* [the italics are mine]. If, however, by some reason or other, the sugar in the blood is increased beyond that normal amount, the excess passes unchanged into the urine. And, the excess in the blood which thus leads to the excretion of unchanged sugar, is so small that we might expect it to be oxidised in the blood did the blood possess any considerable oxidising power." The identity of the idea here expressed with that expressed in the quotation from the author of the article in Hill's "Recent Advances in Physiology and Biochemistry" given in Lecture I., shows how deeply the groundless idea has become rooted in the minds of physiologists.

The misleading nature, upon a vital point, of such a conception cannot be otherwise than obvious to everyone. It implies, contrary to fact, that sugar may reach the blood of the general circulation without its presence being revealed by the urine. The real circumstances are that the urine constitutes an indicator of the state of the blood with respect to sugar, no matter whether the amount existing be large or small, and thence it may be concluded that if sugar were reaching the circulation, as is contended for under the glycogenic theory, it could not escape being rendered evident by the urine, just as indeed happens in connexion with diabetes.

Hôpital Français, 72, Shaftesbury avenue, W C—Resident Medical Officer, unmarried Salary £70 per annum, with full board

Hospital for Consumption and Diseases of the Chest, Brompton — Dental Surgeon

Hospital for Sick Children, Great Ormond street, London, W.C — House Surgeon, unmarried, for six months. Salary £50, with board and residence

Ipswich, East Suffolk and Ipswich Hospital.—Senior House Surgeon. Salary £80 per annum

King Edward VII. Hospital and Dispensary for Windsor, Eton, and District—House Surgeon, unmarried. Salary £110 per annum, with residence, board, laundry, and attendance.

Kingston upon Hull, City and County of—Public Analyst and Bacteriologist Salary £350 per annum.

Liverpool Stanley Hospital.—Third House Surgeon. Salary £60 per annum, with board, residence, and washing

London County Council.—Assistant School Doctors in the Public Health Department. Salary £120 per annum

London Hospital, Whitechapel, E—Medical Registrar. Salary £100 per annum.

Loughborough and District General Hospital and Dispensary —Resident House Surgeon. Salary £100 per annum, with rooms, attendance, board, and washing

Manchester, University of.—External Examiner in Surgery

Milroy Lectures on State Medicine and Public Health — Milroy Lecturer for 1910.

Newark-on Trent Hospital and Dispensary—Resident Medical Officer, unmarried Salary £100 per annum, with board, lodging, and laundry.

Newcastle-on Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum

Norwich, Jenny Lind Infirmary for Children, Unthank road — Resident Medical Officer (female). Salary £50 per annum, with board, apartments, and laundry

Prince of Wales's General Hospital, Tottenham, N.—Honorary Anæsthetist. Also Honorary Medical Registrar

Queen's Hospital for Children, Hackney road, Bethnal Green, E.— Assistant Physician

Queensland Government—Inspector of Insane Asylums and Medical Superintendent of Goodna Asylum. Salary, &c., £800 per annum, with quarters, fuel, and light.

Samaritan Free Hospital for Women, Marylebone-road, N.W — Anæsthetist Salary £20 per annum

Taunton and Somerset Hospital.—House Surgeon Salary £100 per annum, with board, lodging, and laundry

Throat Hospital, Golden square, W.—Assistant Surgeons

University College Hospital, Gower-street, W C — Surgical Registrar

West London Hospital, Hammersmith road, W—House Physician for six months Board, lodging, and laundry provided

West Riding of Yorkshire County Council.—Medical Inspector of Elementary School Children. Salary £300 per annum and actual expenses

Willesden Urban District Council Isolation Hospital.—Resident Deputy Medical Superintendent, unmarried Salary £125 per annum, rising to £200, with board, lodging, and washing

Births, Marriages, and Deaths.

BIRTHS.

Bourdas.—On Nov 14th, at Bedford hill, Balham, the wife of E Clarkson Bourdas, M D, F R.C S E, of a son

Glanville.—On Nov 16th, at Guyon House, Heath street, Hampstead, the wife of W M G. Glanville, B M Oxon, of a son

Godwin.—On Nov 15th, at 35, Southgate-street, Winchester, the wife of Herbert James Godwin, M B, F R.C S, of a daughter.

Lewis.—On Nov 14th, at Weymouth street, W, the wife of Ernest E Lewis, M D, of a son

Reaney.—On Nov 14th, at Kidbrook House, Blackheath, the wife of Captain M. Foster Reaney, M.B, D P.H, I M S, of a son

MARRIAGES.

James—Taplin—On Nov 14th at the Parish Church, Wimbledon, John James, M B Lond, R.A.M C, Woolwich, to Mary Stuckey Taplin, eldest daughter of Mr and Mrs R Taplin, of Thorncombe, Wimbledon.

DEATHS.

Henley—On Nov 14th, at Gloucester, Edward Whishaw Henley, M.R.C S, Medical Superintendent, Gloucester County Asylums, aged 54 years.

Mason—On the 12th inst., Sydney Herbert Mason, M R.C S, L.R C P Lond., aged 35 years, formerly of 333, Moss lane East Manchester, only son of John Mason, The Rowans, Knowle, Warwickshire.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths

During the week marked copies of the following newspapers have been received:—*Belfast News Letter, Edinburgh Evening Despatch, Aberdeen Express, Morning Leader, Leeds Post, The Scotsman, Newcastle Journal, Wolverhampton Express, Blackburn Telegraph, Morning Advertiser, Bolton Evening Mail, Glasgow Record, Manchester Guardian, Norwich Press, Hereford Times, Dundee Advertiser, Belfast Telegraph, Manchester Courier, Birmingham Post, Manchester Evening Chronicle, Notts Guardian, Manchester Evening News, Wolverhampton Evening News, &c.*

Notes, Short Comments, and Answers to Correspondents.

ESPERANTO.

To the Editor of The Lancet.

Sir,—I would like to call the attention of your readers to the advantages of this language to medical men both now and in the future, and to the fact that a universal association of Esperantist medical men has been formed (Tutmonda Esperanta Kuracista Asocio—T E.K.A.), of which the representatives in England are Dr. Richard Legge, County Asylum, Mickleover, Derby, and Mr. Courtenay J. Fuller, 33, Nightingale-place, Woolwich, and that the official journal of this association is the *Voco de Kuracistoj*, which accepts contributions in Esperanto from medical men all over the world. It is, I hope, hardly necessary for me nowadays to occupy your space by dwelling on the ease with which Esperanto can be learned and the useful part which it will play in medicine. If this is not already known to your readers it soon will be. I am, Sir, yours faithfully,

Sydney Whitaker,

Liverpool, Nov. 13th, 1908. Vice-President of the T.E K.A.

SAILORS' HOSPITAL, VENICE

Mr. de Zuccato, the British consul, in his annual report makes reference to the Cosmopolitan Hospital for Sailors which, through the generous efforts of Lady Layard, has been opened in Venice. Her Majesty Queen Alexandra and Her Majesty Queen Margherita have been graciously pleased to consent to become patronesses. H.R H. the Princess Christian of Schleswig-Holstein is the president. The number of sailors sent to the hospital having increased the committee has considered it advisable to have two new wards built with 12 beds for men. A special ward for infectious diseases has also been added. Masters and sailors have all expressed their warm appreciation both of the treatment and of the kind attention shown by the nurses, under the superintendence of Miss Chaffey, the lady superior, who has been awarded two medals for honourable service rendered by her in South Africa. Funds for the sailors' wards would be gratefully received by Lady Layard, Palazzo Capello, San Polo, Venice.

FLIES.

To the Editor of The Lancet.

Sir,—Dr. Delamarre of Paris (*Presse Médicale*, No 66, Nov. 7th, 1908) has lately recommended placing dishes with a 10 per cent. formaldehyde solution about places infested with flies (or mosquitoes) This procedure completely did away with the fly nuisance in large hospital wards, thousands of these creatures being found floating dead on the solution I am, Sir, yours faithfully,

Zurich, Nov. 10th, 1908. Th. Zangger, M.D.

STERILE EMULSION OF IODOFORM.

In the *Pharmaceutical Journal* of Oct. 17th directions are given for the preparation of sterile emulsions of iodoform which are now used as intra articular injections The suggested formula contains iodoform in fine powder 10 per cent. and liquefied carbolic acid 3 per cent. in a mixture of glycerine and distilled water. Ten parts of iodoform are rubbed to a smooth paste with ten parts of glycerine in a sterilised mortar and mixed with the carbolic acid and 20 parts of water After the mixture has stood for 12 hours the liquid is poured away and the remaining paste is mixed with sufficient of a mixture of glycerine seven parts and water two parts to produce 100 parts of emulsion. The ingredients should previously be sterilised by suitable methods. Iodoform may be rendered sterile by shaking one part with two parts of a 10 per cent. solution of formaldehyde in water, or it may be left for three days in contact with a 5 per cent. solution of carbolic acid containing in addition one part of mercuric chloride in 2000 The sterilisation of glycerine may be effected by heating it on a sand bath in a flask for 15 minutes at a temperature of 120° C.

TUBERCULIN.

To the Editor of The Lancet.

Sir,—In reply to the inquiry of your correspondent in your issue of Nov 7th as to the most up-to-date information concerning the use and administration of tuberculin, the information he seeks will be found in "Lehrbuch der Spezifischen Diagnostik und Therapie der Tuberkulose," by Bandelier u Roepke, second edition, Wurzburg, Curt Kabitzsch (A. Stuber's Verlag) An English translation of this excellent book is announced in the preface to be on foot.

I am, Sir, yours faithfully,

London, S W, Nov. 18th, 1908. R. C.

NATIONAL FOOD REFORM ASSOCIATION

This association, which came into existence early in the year, is, we are informed, about to begin active operations against an evil described as the use of improper or insufficient food Undoubtedly questions of diet are of the first importance in health, and anything like an attempt to correct the errors of national diet is a great sociological step forward We wish the association good fortune in its work but trust that the methods of reform which it describes

CHART 1.—Observations on Carrier Mrs. H.

Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.).

FRIDAY (27th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (28th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

them. Arrived at their summer residence the household visited had an outbreak of enteric fever. Either the carrier had been "ineffective" during these nine months or the members of the family had been immunised. The cook found a new situation, and in September, 1906, she caused another outbreak of enteric fever shortly after she arrived, while in January, 1907, another family owed its attack of enteric fever to her entry into the house.

When these outbreaks due to typhoid carriers are mapped out, as in Chart 3, several interesting points appear. It has been already pointed out that the fæces of the typhoid carrier do not always contain typhoid bacilli. Chart 3 shows that the "effectiveness" of the carrier is also intermittent. The thin line on the chart covers the periods when the carrier was in such relation with other persons—generally as a food preparer—as to make infection possible. The shaded areas indicate the times when the potential became an actual infection. For every carrier, therefore, there appear to be periods of maximum and minimum danger, and a knowledge of these times should be of great value in prophylaxis.

Another point which arises during a consideration of Chart 3 is the almost uniform absence of "effectiveness" of the carrier during the early months of the year. The evidence already gained goes to prove that the typhoid bacillus may live for considerable periods in the gall-bladder and hepatic bile-passages, and there is little doubt but that the carrier harbours the typhoid bacillus continuously.

What is the meaning of this period in which the carrier fails to be "effective"? Is it simply coincidence, or shall we find it appearing uniformly when a larger number of cases are available for reference? Has it anything to do with periodicity in the virulence of the bacillus? Does the organism live a "hibernant" existence in the intra- and extra-hepatic biliary passages during these months, and become actively parasitic on re-awakening for the remaining months of the year? Has this "period of effectiveness" anything to do with the type of food taken, or with the general tissue metabolism, or with the heat regulation apparatus? Does this "seasonal effectivity" offer any explanation of the "waves" of endemic enteric fever, the May revival starting the supply of fresh infections which subsequently develop by extension into the autumnal burst? These are questions which call for further observations, and we do not propose to anticipate the replies.

The seasonal waves of typhoid fever are quite characteristic, and the variations in the virulence of epidemics often exhibit "local" features; sometimes, however, the local virulence may assume national characters. We do not know the causes which are responsible for the intensifications of the virus, but evidence is accumulating to show that the human tissues play a definite part. Direct transmission of human fæces at a period of bacterial virulency to water, milk, shell-fish, or other media in which the organism can proliferate is responsible for widespread outbreaks. Human excreta when spread over the surface of soil may prove effective through the agencies of flies or strong wind currents, but it has to be remembered that typhoid bacilli do not proliferate actively in surface soil and cease to be viable after a few weeks (*vide* Mair [2]), so that soil infection probably accounts for a small proportion of cases only. Climatic influences are conjectural; it is possible so to arrange the evidence from Britain, Europe, India, and the tropics that rain, drought, heat, and moisture may be severally indicted. Cold alone occupies an isolated position.

When sporadic outbreaks are contrasted with epidemic human transmission again assumes importance. There is every hope that an intelligent appreciation of this fact by the typhoid convalescent may minimise the occurrence of scattered cases of enteric fever, but it is the obvious duty of the physician to frame rules for the guidance of the patient and to see that they are carried out (*vide* Appendix). Similarly, it behoves the community to protect itself from possibilities of infection by the provision of adequate control over typhoid convalescents. There are certain indications which might be followed until more knowledge points to other pathways.

1. *Systematic examination of the fæces of convalescents or suspected carriers.*—These examinations must be made day by day and extend over long periods. Chart 4 shows that it is impossible to accept any statement as to the periods of infectiveness or freedom from infection unless records of daily examinations are available. Anyone who undertakes this class of work knows that the demands on time, technique, and labour are so great that the community will no doubt adopt the plan of precautionary measures for those convalescents who have contact with foods either in the homes or in the distribution of meat, milk, vegetables, &c., or during the manufacture of cocoa and other eatables, reserving bacteriological measures for the cases whose periodicity does not follow the usual course.

2. *Urine.*—The marked excretion of the typhoid bacilli during the later weeks of the acute attack does not appear to have its parallel in the carrier. We have made a number of examinations of the urine, but they have so far yielded negative results.

3. *Blood.*—The agglutinating properties of the blood may afford evidence of the "effectiveness" of the carrier, but during the attack of Mrs. H. in June her Widal reaction did not vary from the 1 in 25 found on previous occasions. The differential counts we have made in the cases examined yielded an increase of mononuclear cells and this has suggested the need for further observations of a similar nature upon carriers and convalescents. It is quite possible that the extended inquiry may show this to be a valuable adjunct in the determination of "effective" periods.

4. *Temperature and pulse.*

5. *Hands.*—It may be worth while to make bacteriological examination of the nails and fingers. Positive results will exert marked mental effect on those who are requested to take antiseptic precautions after the toilet.

6. *Immunity.*—Determinations of immunity can only be carried out in bacteriological laboratories, but it may be necessary to resort to them in some instances. Speaking generally, the immunity of the typhoid carrier must vary considerably from time to time. It lies near to hand to think of raising the immunity of the carrier by injections of vaccines. Such a procedure will probably minimise the chances of re-infection, so that the carrier becomes less liable to recurrent attacks, but whether the raised immunity will comprise increased bactericidal powers and subsequent destruction of the bacilli is a question which can be answered only when investigations now in progress are more advanced and when our results of treatment with tar derivatives, &c., are available. We do not consider that a typhoid carrier should be considered as "cured" until daily examinations of the fæces have determined the absence of the bacilli during a period extending at least from April to November. This fact is brought out in Chart 4.

We do not attempt to generalise from these necessarily incomplete and preliminary observations, and we venture to hope that the profession, while using prophylactic measures to their full, will not rush into anti-typhoid-carrier therapy until the details have been adequately determined by laboratory investigations.

We are much indebted to Dr. D. Fleck and Dr. R. A. Beaver for their unwearied help in the collection of material and clinical observations and to Mr. J. O. Heaven for collaboration in the preparation of charts.

APPENDIX.

SUGGESTED INSTRUCTIONS TO TYPHOID CONVALESCENTS.

(*To be handed to Patients when discharged from Hospital.*)

view to diminish th

1. The hands and nails should be thoroughly washed, first in disinfectant solution, then in soap and water, and well rinsed before touching any foodstuffs, especially milk.

2. After the bowels are opened or the bladder is emptied the hands and nails should be at once disinfected and washed.

3. Strong disinfecting solution should be poured over the stools, &c., before the plug of the water-closet is used or the lid of the dry closet is shut down.

4. When the motions are loose the risk of infection is increased and additional care should be taken.

5. The convalescent should periodically visit the medical attendant, so that the blood, &c., may be tested, and measures may be taken to

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

In from 18 to 24 hours smears were made from the cultures and stained by Gram's method and with carbol methylene blue and with carbol fuchsin. Subcultures were then made upon agar and nasgar plates and the organisms which preponderated in numbers isolated.

B.—*Results Obtained.*

1. *Trachea.*—Inasmuch as no appreciable amount of mucus can be secured from the trachea in health the only results obtained have been from catarrhal cases. In every one of the cases a coccus was isolated which did not stain by Gram's method. The various cultural reactions in broth, on agar, gelatine, and nutrose ascitic agar (nasgar), as well as the microscopical appearances, indicated that this was an organism indistinguishable from the micrococcus catarrhalis. Cocci staining by Gram's method as well as various bacilli both staining and failing to stain by Gram's method were occasionally found, but were not constant like the micrococcus catarrhalis. It is therefore possible that this latter organism may be the common cause of tracheitis and by downward extension possibly, too, of bronchitis. It must, however, be noted that –Gram cocci are present in 78 per cent. of normal throats and in 68 per cent. of catarrhal throats. The micrococcus paratetragenus described by Roger in 1897, and also found by Bezançon and de Jong[2] in many cases during an epidemic of bronchial catarrhs in Paris in 1904–05, and by Benham[3] in 11 out of 14 cases investigated in Brighton during 1907–08, was not met with.

2. *Throats.*—The bacteriological findings from 23 cases of as healthy throats as could be obtained and from 180 cases of non-diphtheritic inflammatory throats are given in Table I. The results were both disappointing and confusing. As is seen in the table, there were as many diphtheroids, –Gram cocci and Friedländer's bacilli, in the one class as in the other. In neither was the micrococcus paratetragenus ever seen in films or cultures.

TABLE I.

	Healthy.		Inflammatory.	
Diphtheroids	39 per cent.		38 per cent.	
Bacillus septus	35 ,,	39 per cent.	29 ,,	38 per cent.
Hoffmann's bacillus	4 ,,		9 ,,	
– Gram cocci	78 ,,		68 ,,	
+ Gram cocci	70 ,,		83 ,,	
+ Gram bacilli	40 ,,		40 ,,	
Bacillus of Friedländer	4 ,,		3·3 ,,	

Two points may, however, be noticed. First, the question of virulence and pathogenicity could not be determined; and secondly, my figures for diphtheroids in normal throats is very much higher than that found by most authorities—viz., about 8 per cent. Whether the small number of cases examined (23), the class of patient (medical students and out-patients at hospital), or the time of the year (January and February) is responsible for this great divergence I am unable to say. In a series of 20 cases of slight sore throat accompanied by cold in the head or tracheal cough either diphtheroids, or –Gram cocci, or both, were present in every instance, and I can only express the belief that these organisms are concerned in the production of sore throats. Dr. M. H. Gordon by the accidental absorption through a pipette of an emulsion of micrococcus catarrhalis has established the fact of this organism being capable of doing so.

3. *Noses.*—The difficulty of securing reliable bacteriological examinations of normal nasal cavities is great in London as so few people fail to give a history of recent colds; in the case of 20 as normal noses as were obtainable the following were the results of the alternative method mentioned under 3 (*b*). None were absolutely sterile but five only yielded air organisms such as sarcina lutea and aurantiaca, 10 gave only +Gram-staining cocci, six of these being staphylococcus albus, two staphylococcus aureus, and two staphylococci albus and aureus. From the remaining five cases in addition to Gram-staining cocci, the bacillus septus was obtained in one, and cocci failing to retain the stain by Gram's method and belonging to the pseudo-catarrhalis group in the other four. Air organisms were also present in most of these 15 cases. Of published observations elsewhere may be mentioned those of Hasslauer,[4] who examined 111 cavities and found staphylococcus pyogenes albus in 25 per cent., pneumococcus in 20 per cent., streptococcus pyogenes in 17 per cent., and diphtheroids in 13 per cent., more than one and not more than three or four different organisms being present. Von Besser[5] examined 81 cases and found staphylococcus pyogenes aureus in 17·5 per cent., pneumococcus in 17·5 per cent., streptococcus pyogenes in 8·7 per cent., and Friedländer's bacillus in 2·5 per cent. Lewis and Turner[6] examined 26 specimens from 16 persons; only three of these were sterile, in 13 only one organism was present, in nine two organisms only, and in one three organisms. On investigating the pathogenicity of the organisms which they isolated these last observers found that the organisms derived from nine healthy noses were non-pathogenic to animals, and in two cases they were pathogenic, and the conclusion was arrived at that not only are the organisms present only in small numbers but that their virulence and vitality alike are low.

The bacteriology of the mucosa in 42 cases of colds investigated in London during the years 1905, 1906, 1907, 1908.—The results which I have obtained in 42 cases of colds are given in tabular form in Table II.; only the presence of organisms which may be regarded as possibly causal is indicated. A few cocci staining by Gram's method and occasional non-pathogenic air organisms were also found in the cultures, but once identified as such were then disregarded. It will be seen that only one of the four organisms was present in the great majority of the cases. In Nos. 2 and 6 (Table III.) a very few of the second organisms were present, while in Nos. 11, 13, and 21 two organisms were found in about equal numbers; these last three cases were of a specially severe type.

TABLE II.

Bacillus of Friedlander alone	In 8 cases	=	19 per cent.
,, influenzæ ,,	,, 1 case	=	2·4 ,,
,, septus ,,	,, 11 cases	=	26·2 ,,
Micrococcus catarrhalis ,,	,, 12 ,,	=	28·6 ,,
Bacillus of Friedlander + bacillus septus	,, ,,	=	7·1 ,,
Bacillus of Friedlander + micrococcus catarrhalis	,, 2 ,,	=	4·7 ,,
Bacillus septus + micrococcus catarrhalis	,, 4 ,,	=	9·7 ,,
No definite organism isolated	,, 1 case	=	2·4 ,,
Total number of cases	42		

Too much importance must not be attached to the percentage figures given, although the results are obtained from observations spread over nearly four years. The bacillus of Friedländer is, I think, thereby made out to be a more frequent cause of colds than it really is, while the figures for bacillus septus and micrococcus catarrhalis are too low. By studying, say, 50 cases in any given epidemic results totally at variance with these might be obtained and a percentage value of even 100 obtained for either the bacillus septus or micrococcus catarrhalis. It is due to this fact that the claims of these organisms have been unduly pressed at various times by different observers. The rarity of the bacillus influenzæ and the total absence of the micrococcus paratetragenus are alike striking in the above series; this is probably due entirely to the fact that London was not affected by epidemics due to either of the above micro-organisms during these years.

C. *Justification of the View that Colds are Due to the Organisms Indicated.*

It may well be asked what grounds there are for regarding these several organisms as even being capable of producing colds, and still more especially of having produced the particular attacks here indicated, inasmuch as it has been shown that the micrococcus catarrhalis and closely allied forms are frequently resident in the healthy tract, that the bacillus of Friedländer is present in between 2 and 4 per cent. of healthy noses, and that diphtheroids infect from 8 to 12 per cent. of noses and throats presenting no pathological features. To this it may be replied that from a certain percentage of normal throats pneumococci or the Klebs-Löffler bacillus may be similarly isolated and may even

Three Lectures

ON THE

PATHOLOGY AND TREATMENT OF DIABETES MELLITUS, VIEWED BY THE LIGHT OF PRESENT-DAY KNOWLEDGE.

Delivered before the Royal College of Physicians of London

BY F. W. PAVY, M.D. LOND., LL.D. GLASG., F.R.S.,

CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

LECTURE II.[1]

Delivered on Nov. 12th.

MR. PRESIDENT, COLLEAGUES, AND GENTLEMEN,—In my "Physiology of the Carbohydrates," published in 1894, I brought forward a new view with respect to the disposal of the food carbohydrate within the animal system. The clue was given to it by the work which had shown that carbohydrate entered into the constitution of protein matter. By general assent, it is now admitted to do so, and thus a new position is created, providing for the application of carbohydrate in a manner that had not previously been thought of. We know that the carbohydrate of the food is to be traced to the seat of absorption in the walls of the alimentary canal, where it presents itself in the form of sugar. What now becomes of it? If it passed straight on as sugar into the blood, it ought to give rise to glycosuria in the healthy state in like manner to what occurs in diabetes. From the line of experimenting, to which reference was made at the conclusion of the previous lecture, involving the removal of the liver from the field of action, we are driven to conclude, in order to account for the existing circumstances, that there must be an influence at work at the actual seat of absorption to arrest the onward passage of sugar, as such, towards the circulation.

As set forth in my published work referred to, conditions are found at the seat of absorption that suffice satisfactorily to account for the disappearance of sugar that is here observed to occur. We have, in the first place, the fact to deal with that, as can be shown by the effect of cleavage agencies, carbohydrate can be cleaved off from its locked-up state in protein, and in the next, that carbohydrate can, in the presence of nitrogenous matter, be built up into protein by the instrumentality of the synthetic power inherently belonging to bioplasm. Now, nowhere do we find such activity of protein formation existing as at the seat of intestinal absorption. Quiescence prevails at a period of fasting, but after food ingestion, extremely active bioplasmic growth starts into operation, the newly-formed bioplasm flowing, in the shape of lymphocytes, through the chyliferous vessels into the circulatory system, and giving rise to the digestion lymphocytosis which is observed to follow the ingestion of food.

Everything points to the occurrence of a

DISAPPEARANCE OF SUGAR AT THE SEAT OF ABSORPTION,

and with such an occurrence, everything falls harmoniously into line, both in relation to the conditions observed in connexion with the normal state and those observed in connexion with diabetes. But to what extent is it possible for sugar to become lost to view in this way? It is true, with our rough chemical methods put in operation outside the body, only a comparatively limited amount of carbohydrate is to be obtained from the disruption of protein, but it is evident that this is not to be taken as a measure of what may actually exist incorporated within.

Ground is given for the statement made through what is observed in the glycosuric state, induced alike by pancreas extirpation and the action of phloridzin, when the point is reached at which the eliminated sugar is solely derived from protein disintegration. The output of nitrogen being estimated, as well as the sugar, means are afforded for determining the protein destruction occurring. At first the output of sugar is large and variable in proportion to the nitrogen, on account of being partly derived from the carbohydrate (glycogen) existing in a free state in the body. In the course of time, with the observance of fasting, this becomes expelled, and then a fixed relationship is found to present itself between the outgoing nitrogen and sugar. From the nitrogen obtained, the amount of protein disintegrated can be calculated, and thus the data are given for determining the relation subsisting between

PROTEIN DISINTEGRATION AND SUGAR LIBERATION.

Reckoning upon the basis of the information in this way supplied, it may be roundly stated that protein yields up about half its weight of sugar, which may rationally be taken to have been previously incorporated with it from the food.

The disappearance of absorbed sugar by synthesis into protein before passage from the mucous membrane of the intestinal canal, harmoniously fits in with the absence of glycosuria as a result of Eck's fistula. With sugar locked up in protein reaching the general circulation through the lacteal system, the position is unaffected by the experimental prevention of the passage of the portal blood through the liver. Only a variable portion of the absorbed sugar would be left to find its way into the portal blood. I expressed myself upon this matter in my recent work on "Carbohydrate Metabolism and Diabetes," p. 66, 1906, in the following terms, and the remarks were made before the information supplied by Eck's fistula had been taken into consideration. "As yet I have only spoken of the assimilation of carbohydrate by being built up into proteid through the agency of bioplasm. Probably, when there is no particularly large supply of carbohydrate to be dealt with, this is the main result that occurs. When, however, the supply is extensive, it is evident that some escapes being disposed of at the seat of absorption, and thence reaches the portal blood. At a period of fasting, and likewise after the ingestion of animal food, the portal blood, as regards the amount of sugar present, corresponds with that belonging to the other parts of the circulatory system. After a free supply of starchy food, however, sugar may be found to be present in the portal blood to a considerably larger extent than anywhere else."

What is contended for then is that the main

DISPOSAL OF THE ABSORBED SUGAR

is effected by the assimilative action occurring within the mucous membrane of the intestinal canal, and that what escapes being disposed of here, passes through the portal vein to the liver, which exerts a supplementary action in checking its flow into the general circulation by producing transformation into glycogen. The conditions existing in connexion with Eck's fistula are of a nature to affect the latter action, and not the former, and thence it follows that as long as the ingested carbohydrate falls within the capacity of being disposed of at the seat of absorption in the walls of the alimentary canal, there will be no passage of sugar occurring into the general circulation, and, as a consequence, no glycosuria; but if the carbohydrate stands beyond the capacity referred to, sugar will be reaching the portal vein, and, passing through Eck's fistula, will flow into the general circulation and constitute the source of glycosuria. Now, according to the statement made by De Filippi upon the strength of his experiments with Eck's fistula, glycosuria was not observed after the administration of starchy food, but was observed after the administration of sugar when the quantity given reached a certain point which stood below that which was found to be required to produce glycosuria in the normal state, which means the existence of a diminished tolerance.

It is seen from the experiments recorded in my "Physiology of the Carbohydrates," p. 105, on the condition of the portal blood after the administration of carbohydrate food that, in the dog, there is in no instance any great effect produced on the sugar content. In the rabbit it is otherwise. In some of the instances in this animal, the figures after food come out conspicuously high. The highest in the list stands at 4·590 per 1000 before hydrolysis and 5·330 after. In many of the others, only a somewhat slight increase is observable. The tendency of the operation would be to give higher figures than for the actual circulating state, on account of the blood being somewhat delayed in the capillaries and instances - Gram *cocci* which may have been *micrococcus* catarrhalis were seen, and in two cases isolated and proved to be the micrococcus catarrhalis, so that Benham's deductions may be entirely misleading, as may also be those of the other observers above referred to. A consideration of the occurrence in catarrhal affections of the eye and urethra of its close ally, bacillus xerosis, still further weakens its claims. Pathologists no longer regard this as a pathogenic organism, yet in the healthy eye and healthy urethra it is not commonly present, whereas in catarrhal conditions set up by the Koch-Weeks and Morax-Axenfeld bacilli and by the gonococcus it is practically omnipresent (in between 95 and 99 per cent. of all cases). My figures—in 9 out of 20, or 45 per cent.—moreover show that it may be a very common inhabitant of the non-catarrhal throat. Distinct evidence of the pathogenicity of the bacillus septus is therefore very necessary and is so far entirely lacking, despite several attempts at demonstration. Despite these facts certain considerations induce me to think that it is a factor in the production of colds. In 11 out of my 42 cases this organism was present in almost pure culture—at least, despite the use of such culture media as blood agar, blood serum, and nutrose ascitic agar I could find no other organism recognised as the possible cause of a cold. The cold and organism disappeared together. Further, in the instance of Case 17, a medical man and close observer, suffering from an acute attack, to which he was very subject and which always continued subacute for several weeks, I isolated this organism and made a vaccine for the patient. Upon the sixth day when he felt very ill I injected him with 275,000,000 dead organisms. On the next day he was better, and on the following day he was quite well, while his index rose from 0·9 to 1·7. Again, a friend who travels much by rail and always catches cold and sore throat on these occasions, upon several of which I isolated the bacillus septus, was about to undertake a long train journey; he welcomed the suggestion of an inoculation and was given 275,000,000 dead organisms. Despite a long and very cold all-night journey, for the first time for years he developed neither sore throat nor nasal catarrh, nor during the succeeding 12 months has he developed a cold at all. Close attention to the clinical symptoms in my cases has revealed the fact that the bacillus of Friedlander rarely, if ever, produces a sore throat. In Cases 6, 13, and 21, in which both the bacillus of Friedlander and the bacillus septus were found a sore throat was a prominent feature, and out of the 11 cases in which the bacillus septus alone was found, ten had pronounced sore throats as the earliest symptom. It would therefore appear that the chief rôle of the

blood, as is exemplified by the occurrence of peptonuria and albumosuria.

Under the view referred to, it has been considered then, alike for protein and carbohydrate, that the food-supply, after being brought by enzyme action into a small molecular state, is in this state conveyed *through the circulation* to the tissues to be taken in a direct manner on by them, and then utilised. This is tantamount to placing the blood, as far as its office in connexion with food transport is concerned, into the position of an agglomeration of small molecules emanating from food digestion. Why, under these circumstances, should the elaborated protein constituents met with in the blood exist? We have been accustomed to look upon these ingredients as constituting the pabulum from which the tissues draw their nutrient supply, but how does this stand in face of the contention that the food-stuff is conveyed direct to the tissues in the form of broken-down products of digestion?

The subject matter that is before us constitutes a deeply *important link in the chain of events connected* with the passage of food to utilisation in the body. It also has a collateral bearing in connexion with the urine, inasmuch as the state of the urine is dependent upon the character of the constituents of the blood with respect to molecular size of its ingredients; and through this, the particular form in which the food-stuffs are transmitted from the seat of absorption to that of utilisation in the tissues is brought into relation with the

QUESTION OF LIABILITY TO ESCAPE WITH THE URINE,

in their passage through the kidney, in an unutilised state, or, on the other hand, their non-liability to do so, in which case retention for service in the system, instead of loss, is provided for.

The question of liability or non-liability to escape in the transit of the blood through the kidney is of sufficient importance to lead me to consider it compulsory to give consideration to a view which has been recently broached regarding the state in which the products of food digestion are conveyed through the circulatory system to the tissues. The view, it is true, relates to the protein portion of food, but it being considered that the line of procedure for the carbohydrate portion is of parallel nature to that for the protein, the discussion has a signal bearing on the subject of these lectures.

It was formerly taught that the digestion products issuing from the fatty and albuminous principles of food, reached the circulation through nature's specially constructed channel placed in connexion with the absorbing mechanism of the alimentary canal. Some 30 years ago, a changed idea was put forward upon the strength of experimental results obtained by Schmidt-Mülheim. In the experiments performed, the urinary nitrogen from nitrogenous food was estimated after obstructing the flow of lymph and chyle into the circulation, and compared with the amount found when the connexions between the absorbent and vascular systems were free. It appeared that no essential difference was discernible, and thence it was inferred that protein matter found its way from the alimentary canal into the circulation by passage through the walls of the vessels belonging to the portal system instead of through the thoracic duct.

Notwithstanding the incompatibilities involved in such a view it is surprising the extent to which it became adopted. In face of the settled knowledge possessed regarding the resistance offered to the transmission of proteins through membranes, we find that the portal vessels are freely talked of as constituting the

CHANNEL FOR THE PASSAGE OF PROTEIN EMANATING FROM THE FOOD

into the circulation. Still more strikingly in defiance of reason, we even find, amongst recently recorded work, an observer looking in the mesenteric veins for the lymphocytes emerging from the villi and supposed to pass, as the natural course taken, through the adjoining capillaries into the portal blood! Picture a lymphocyte forcing its way from a lymphoid lacuna through the membranous walls of a capillary, against the blood pressure existing within!

In the case of protein, with equal pressure on both sides of a capillary wall, the conditions are of a nature to prevent the passage of its molecules either way. If this is so with the equal pressure to deal with, is it permissible to conceive that protein can take the course suggested against the blood pressure existing within the vessels! With a reversal of the circumstances, however, the protein molecules can, and do, pass through in compliance with what is observed under ordinary physical conditions to occur. As a matter of fact, under the influence of the blood pressure within the capillaries, protein transudes into the lymph spaces. It does so in proportion to the existing pressure, and leucocytes even do the same, accounting for the migration that is known to occur. Physical laws permit of these procedures, but are altogether opposed to the idea of passage of protein in the reverse direction—namely, from the lymph spaces into the blood-vessels.

Since the discovery of erepsin, the enzyme which has the power of carrying the hydrolysis of the proteins on to the amino-acids, another view *has sprung up regarding* the procedure by which the proteins are rendered available for appropriation by the tissues. It embodies no less radical an alteration than the

PASSAGE OF PROTEIN IN THE STATE OF BROKEN-UP FRAGMENTS

consisting *of amino-acids through* the circulation to the tissues. Professor W. D. Halliburton has espoused this view and introduced it into the last edition of his "Handbook of Physiology." It is claimed by him that the proteins become hydrolysed at the seat of absorption into the amino-acids, and that these pass straightway into the blood and thence to the tissues where they become linked on to the tissue molecules and applied to the purposes of life.

Protein is thus assumed to be brought into a smaller molecular state than that of albumose and peptone for transmission through the circulation to the tissues. The conditions are parallel to the transmission of carbohydrate through the circulation in the form of sugar, and what applies to sugar running off with the urine, in proportion as it is present in the blood, will equally apply to the amino-acids. The amino-acids do, as a matter of fact, show themselves in the urine in association with the existence of certain pathological states, so that proof is not wanting that, as might be expected on account of their small molecular size, when they are demonstrably present in the system they become equally so in the urine. The existence of these acids in normal blood and urine constitutes a disputed point, and to overcome the difficulty here arising the convenient assumption is advanced that they are taken by the tissue cells as fast as they can reach the circulation. The same kind of argument has been applied in the case of sugar and we know that it does not here hold good.

In this, as it appears to me, extraordinary contention that the broken-down protein of food is conveyed through the circulation in small molecular fragments to the tissues to be there reconstructed into the specific protein belonging to the animal, the proteins of the blood are left out of consideration altogether, although good grounds exist for looking upon them as a pabulum from which the tissues draw their nutrient supply.

The new position that has been taken by Professor Halliburton contrasts strongly with that which he formerly held. In his "Handbook of Chemical Physiology and Pathology" published in 1891 he says (p. 337): "The increased percentage of proteids in the chyle as compared with the lymph illustrates the fact that the lacteals are not merely concerned in the absorption of fatty, but probably also of albuminous food. In the stomach and intestine the proteins of the food are converted into peptones, substances that diffuse with readiness through living membranes; but no peptones (or proteoses, the intermediate products in the formation of peptones) are found in the chyle; during their passage through the intestinal wall, or immediately on entering the lymph or blood stream, they are reconverted into albumin and globulin." This stands in accord with the view that was at the time generally held. Indeed the only unsettled point then engaging the mind was the question that had been raised by Schmidt-Mülheim's ligature of the thoracic duct experiment which bore upon the path through which the passage of the reconstructed protein took place, in connexion with which Professor Halliburton thus wrote: "Schmidt-Mülheim tied the thoracic duct in dogs and found that proteids were still absorbed; this however does not prove that the lacteals are not normally concerned in the absorption of proteid: it merely shows that animals thus treated can continue to absorb proteid by the other path—the blood-vessels."

Passing now to the last edition of Professor Halliburton's

Klebs-Löffler bacilli, yet develop neither pneumonia on the one hand nor diphtheria on the other.

Age.—Colds are the more dangerous to the very young and the very old, but age seems to have no influence whatever upon the incidence of an attack.

Conditions of life.—Those who live much in the open air certainly seem less liable to colds than those who live in cities, but poverty and wealth seem to have but little bearing. Colds are no respecters of persons; if anything the rich are more liable than the poor, or, at all events, they make more of their colds. With a view to ascertain the influence of fatigue and lack of food, upon one day in winter I did without food all day, took excessive exercise, returning home covered with perspiration. Quickly stripping I then stood hot and exhausted at an open window for ten minutes till thoroughly chilled. Although the bacillus of Friedländer was then in my nose, as I had proved the day before, no cold developed. A fortnight later, warmly clad and well fed, I caught an unsought-for cold.

Opsonic index.—Reference to the chart of Case 1 will show that a high opsonic index is no protection against an acute attack, for such supervened when the index stood at 1·56, at 1·36, and again at 1·5. Anything which will, however, cause a sudden lowering of index will probably predispose to an attack. As I will show presently, the tissue plasma has a higher index than that of the blood. It seems probable, then, that local reduction in the index of the tissue plasma of the nasal mucosa is an important adjuvant to infection. How this can be brought about I know not, but can only suggest that local vaso-motor disturbance may play an important part, for one of the earliest symptoms of approaching catarrh is great congestion of the nasal mucosa. This is purely reflex, for it can often be removed by setting up another reflex, as by hanging the head out of an open window, sponging the skin of the body with cold water, or if the affection be unilateral by merely inclining the head to the opposite side. This view is in accord with the universal experience that the onset of a cold may often be determined by a cold draught of air striking the back of the head for a very few minutes. To this question of vaso-motor disturbance reference will again be made under the question of cure. That infection is accompanied, or more probably preceded, by a fall in the opsonic index and recovery by a rise is well shown by the following observations upon Case 1. About six weeks after treatment with a vaccine and cure of the long-standing chronic nasal catarrh a specimen of blood was taken. About 12 hours later all the symptoms of an oncoming acute cold began to develop and a second specimen was taken. Next day the cold had completely aborted and a third sample of blood was obtained. The indices of the three were then found to be as follows: before the onset of the cold, 2·6; at the onset, 2·0; and when the cold had aborted, 5·8. The cause of the spontaneous and speedy recovery was thus very evident.

The influence of the daily processes of life, such as the morning bath, meals, exercise, and rest, upon the opsonic index was also studied. With this end in view specimens of blood were taken at the following times and their indices were determined: (1) immediately on rising; (2) a quarter of an hour after the morning bath; (3) two hours after breakfast; (4) at 4 P.M.; (5) at midnight, i.e., after completion of digestion of dinner and after an evening walk; and (6) at 3 A.M., i.e., after three hours' repose. The results obtained, being the numbers of organisms taken up by 100 polymorphonuclear leucocytes, are set out in the following table:—

Table V.

Date.	1	2	3	4	5	6
15/5/06	380	402	435	—	—	—
15/5/06	317	351	380	—	—	—
29/5/06	680	736	733	810	861	—
1/6/06	165	150	134	—	—	—
6/6/06	534	571	—	—	626	536
12/6/06	375	413	—	—	427	—

From this we see that there is a steady gradual rise throughout the day, a maximum seemingly being attained after digestion of the main meal of the day has been completed and after a full day's exercise has been taken. During the night the index steadily falls and from the determination of 6/6/06 would seem to reach a minimum by 3 or 4 A.M.

Experiments into the causation of this diurnal variation.—Assuming it, then, to be a fact that the opsonic index of the blood to various organisms rises during the day and falls during the night, the question arises as to the causation of this. The digestion of a meal is said to result in a tidal increase and decrease of the alkalinity of the blood, owing to the secretion of hydrochloric acid during digestion in the stomach and of alkalies during digestion in the duodenum. Exercise is said to result in decrease in the alkalinity of the blood owing to the formation of acids by the muscle metabolism. Observations were made to see whether an alteration either in the way of increase or decrease in the alkalinity of the serum had any influence upon the opsonic index. The normal alkalinity of the blood is between N/25 and N/30, say N/28. To one volume of blood serum were accordingly added (1) one volume of distilled water giving an alkalinity of N/56, (2) one volume of N/28 caustic soda giving an alkalinity of N/28, and (3) one volume of N/56 hydrochloric acid = N/112. These diluted sera were then used as if they were normal sera and comparison was made of their opsonic power, with the result (counts are numbers of organisms in 50 cells):—

Table VI.

Date.	Serum.	Alkalinity.		
		N/28	N/56	N/112
		Index.	Index.	Index.
8/6/06	1	71 = 1	47 = 0·66	66 = 0·93
—	2	36 = 1	68 = 1·89	53 = 1·75
12/6/06	1	675 = 1	641 = 0·95	462 = 0·68
16/6/06	1	134 = 1	174 = 1·30	200 = 1·49
—	2	176 = 1	169 = 0·96	190 = 1·14
—	3	139 = 1	189 = 1·35	138 = 1·00
		6·00	7·11	6·99

It will be seen that no constant effect was produced; it would, however, appear that a reduction in the alkalinity of the blood serum has a slight effect in raising the opsonic index. This is in accord with the findings of Hektoen and Ruediger[16] that sodium bicarbonate among chemical bodies is a non-specific anti-opsonin. Lactic acid, again, is another such body; it may therefore be assumed that the accumulation of lactic acid in the body, as occurs during excessive muscular fatigue, will also conduce to infection. So well equipped is the human body with means to cope with disturbances in any of its functions that it is obvious that only when these disturbances are unusually great will the protective mechanism be broken down and predisposition to infection be established.

(To be continued.)

A CASE OF LICHEN PLANO-PILARIS IN WHICH THE SPINOUS ELEMENT PREDOMINATED.

By AGNES F. SAVILL, M.A. St. And., M.D. Glasg., M.R.C.P. Irel.,
ASSISTANT PHYSICIAN TO ST. JOHN'S HOSPITAL FOR SKIN DISEASES, LEICESTER SQUARE.

At the end of April, 1908, a married woman, aged 30 years, consulted me at St. John's Hospital for Skin Diseases, Leicester-square, concerning an eruption which she first noticed about six weeks previously. She had two children, five and two years old respectively. The patient considered herself to be a healthy woman, but had recently felt unusually fatigued and nervous.

Family history.—The patient's mother had died from consumption at the age of 34 years. There was nothing further by them. No doubt, in connexion with life, there is a power in operation of a determining or regulating nature, which leads to the performance of operations which cannot spring from mere chemistry and physics, but observation teaches us that this power manifests itself upon matter through the instrumentality of chemical and physical actions.

---

[16] Journal of the American Medical Association, May, 1906.

The absorbent system may be considered to pick up the unappropriated material which has escaped from the blood vessels for the purpose of tissue nutrition, and to convey it back in the form of lymph to the circulatory system. At a period of fasting, such is the nature of the fluid present in all parts of the absorbent system. At a period of digestion, however, the absorbents belonging to the alimentary canal become charged with products derived from the food, which thus supplement the contents that are ordinarily present, and far outweigh them in quantity and significance. We have, then, a product of absorption from the food, which visibly presents itself to our notice, and naturally passes into the blood stream through the thoracic duct.

Let us pursue this matter further and see how the evidence stands bearing on the

PASSAGE OF RECONSTRUCTED PROTEIN FROM FOOD INTO THE CIRCULATORY SYSTEM.

There is no question about the contents of the thoracic duct flowing into the blood stream. What do these contents consist of? At one time, lymph, and at another time, chyle: the former, representing the unutilised exudate from the blood for the nutrition of the tissues, and the latter, this exudate plus material derived from the food. Seeing that the exudate is likely to be, and, as a matter of fact is, very variable in quantity consequent upon the extent to which it is influenced by varying conditions, and that the food item is of a variable nature, it is not surprising to find that much difference exists in the estimates given of the amount of lymph and chyle flowing into the blood.

Amongst text-book authorities, Michael Foster speaks of its having been calculated that in a well-fed animal, a quantity of lymph and chyle equal to that of the whole blood may pass through the thoracic duct in 24 hours, and that of this, about half comes through the lacteals from the abdominal viscera, and therefore to a large extent from food. Upon this basis he reckons that for a man of average weight the quantity discharged into the blood per hour would be a quarter of a kilogramme, or a little under a quarter of a litre, a ratio giving something less than six litres for the 24 hours.

It is a matter that is beset with difficulties to obtain precise information experimentally regarding the rate of flow taking place under natural conditions. Hence many widely conflicting statements have been made by different authorities. Cases are from time to time come across in the human subject where from some unnatural condition connected with the thoracic duct an obstruction is offered to the flow of chyle in its proper direction and it becomes discharged from the lymphatics belonging to a particular portion of the skin.

One such case has recently formed the subject of a communication from the physiological laboratory of University College, London, by J. Molyneux Hamill in the *Journal of Physiology*, Vol. XXXV., 1906. The patient, who was an inmate in University College Hospital, was a man in a fairly healthy state, 20 years of age, and 140 pounds in weight. When a boy of 10 years, the cutaneous lymphatic distension showed itself and led on to the formation of a permanent fistulous opening in the upper part of the right thigh close against the groin. Through this opening lymph and chyle, when not controlled by a pad and bandage, escaped. When escape was prevented, accumulation took place in the affected parts and led on to a state of tension which required to be from day to day relieved by allowing a certain amount of exit to take place. An observation was conducted on

THE RATE OF CHYLE FLOW

by leaving the opening free and allowing the chyle to trickle into a vessel placed to receive it. In this way, over four litres, it is stated, were collected in the course of 12 hours. Further escape was then stopped at the patient's request owing to the great exhaustion it produced. It is seen that the rate of flow was here greater than in the estimate given by Michael Foster. At the same time, however, the collected fluid, it is to be remarked, was considerably more watery than lymph and chyle collected in a direct manner.

Whatever may be the exact volume of liquid flowing from the absorbent into the vascular system, it is evident that it is one of considerable magnitude, and upon this point there is no need here to say more. In pursuing the train of reasoning in hand, I will pass to the consideration of the component nature of the current that flows into the blood. It is closely allied in constitution to the blood itself, and may, in fact, be said to represent rudimentary blood, minus the red corpuscular element. Fat in suspension is present as a collateral ingredient when absorption of fat has taken place from the alimentary canal. This principle, not being mixed up with the point before us, need not be further alluded to. The point of special concern is the presence of lymphocytes, as in blood, and of protein matter precisely under the forms met with in the blood—viz., as albumin, globulin and fibrinogen.

Professor Halliburton in his "Handbook of Chemical Physiology and Pathology," 1891, p. 331, speaking of lymph plasma says: "It may be briefly described as diluted blood plasma." With respect to distinction between lymph plasma and chyle plasma, it is generally admitted that the latter contains a larger percentage of protein than the former, and this falls in accord with the view expressed by Professor Halliburton in the quotation a short time back given from p. 337 of the work I have just referred to.

The flow from the absorbent system, then, carries

PROTEIN MATTER, THAT BECOMES BLOOD PROTEIN,

in company with lymphocytes into the blood stream. I consider it is not justifiable to conceive that the exudate from the blood into the lymph spaces is at all comparable to the product which passes from the absorbent system into the veins. An opportunity is afforded of seeing the comparatively watery character of the lymph space fluid when the quantity is preternaturally augmented as in dropsical conditions, and here, on account of the increased blood pressure in operation, the circumstances are such as even to promote more transudation of protein matter from the blood than is occurring naturally.

The conclusion to be drawn is that protein becomes developed within the absorbent system, and we have an elaborating agency present that suffices to accomplish the work. The lymphocytes represent bioplasmic growth, and it is the property of growing bioplasm to link on molecules of suitable configuration from around it and incorporate them into its substance. It may be reasonably conjectured that the plasmic material not appropriated by the tissues becomes taken up by the lymphocytes, and, in a re-elaborated state, thence restored to the circulation.

Such is what may be said regarding recovery and restoration to the blood, in protein form, of transuded and unapplied nutrient material. Let us next look at what occurs in connexion with the transport of food. It is beyond dispute that food protein is, in the first place, broken down and placed in a position to be capable of diffusing through the innermost layer of the intestinal canal into the subjacent lymph spaces. This is all that is here wanted, and, as far as the process in question is concerned, it is immaterial whether the breaking down stops, as has hitherto been believed, at peptone, or whether it passes on to the amino-acids. For the next step, a necessary condition is that the molecules produced should be susceptible of being taken on by the growing bioplasm with which they come into relation. If this condition is complied with, all that is wanted is here again, at this further stage, supplied.

Let it be supposed that food protein has been broken down and put into a diffusible condition, and that the molecules produced possess the requisite configuration to adapt them for being taken on by the molecules of bioplasm, within the reach of which they may happen to fall. What, it may be asked, next occurs? The view formerly held and systematically taught was that

A RE-SYNTHESIS INTO PROTEIN

was effected by the epithelial cells of the intestine, and that the regenerated protein, in some inexplicable way, made its escape from the cells, and then, upon the strength of the notion started by Schmidt-Mülheim's experiments and in opposition to recognised physical laws, reached the circulation by direct transmission through the walls of the capillaries of the portal system.

Now, besides the bioplasm belonging to the epithelial cells, there is another form of bioplasm present in close of sections were cut from the excised portion of skin, so that the microscopic appearances could be observed both where the follicles were chiefly involved and where the intervening skin showed the slight degree of congestion above mentioned between the follicles. The photograph here reproduced (Fig. 2) shows one of the sections through a congested area of skin. A typical small early papule of lichen planus is seen, exhibiting the increased horny layer, marked stratum granulosum, (*l*) commencing hyaline change of the epithelium, obliterated interpapillary processes, and the underlying œdema and mononucleated infiltration of the papillary body. The clinical appearance of the part had not led one to expect any such histological appearance. On the left side of the section are two depressions which further sections proved to be follicles. Attention is called to the fact that these follicles are filled with lamellæ of horny material, and the epithelium otherwise exhibits the changes usually found in a flat papule of lichen ruber planus, having a marked stratum granulosum, swollen epithelial cells, œdema of the papillary body, and a degree of surrounding infiltration with small and large mononucleated cells. Another distended follicle in the same section, not shown in the illustration, exhibited no alteration in the epithelial cells and no surrounding infiltration. Further sections taken from the same patch revealed a different stage of the process. There were numerous follicles distended with horny material, and the intervening skin showed no trace of any lichen planus papules. In certain of the follicles there was at the blind end a degree of epithelial degeneration such as one finds associated with the flat lichen planus papules, but in certain other follicles which were equally distended with increased horny material there was no abnormal alteration of the deeper epithelial layers. Mononuclear-celled infiltration was present only around a few of the follicles and only at the lower blind end. The blood-vessels of the cutis in the vicinity of the follicles were somewhat dilated. There was no polynuclear cell infiltration either around the follicles or the blood-vessels.

Summary of case.—The interest of the case lies in the fact that it presented so many totally distinct clinical lesions at the same time, and that these were observed from week to week in process of development and again of retrogression. 1. There was a clear history that the advanced lesion on the thigh had started as groups of grey spinous lesions similar to those of later origin observed on the chest. 2. The lesions on the arm were seen to start as small papules of lichen planus without any spinous or follicular lesion either at the beginning or at any stage of their growth and final progress to complete recovery. 3. During the six weeks after the end of April the disease progressed; a pink tinge was seen gradually developing around the mouths of the groups of follicles from which horny spines protruded, and also in some parts of the intervening skin. When a new form of treatment was instituted in June the disease ceased to progress; the rosiness gradually faded away before the pinkness had acquired any clinical appearances of a lichen planus papule, but the microscope revealed that the congestion between the follicles was in reality an early stage of lichen planus. (Fig. 2.) Without the form of treatment started in June the lesions on the chest would undoubtedly have undergone the same change as had occurred in the thigh, where there was a large patch of chronic lichen planus studded with prominent and thick grey spines. It is also a matter of interest that at no time and in no position was there seen an acuminate papule of lichen planus, such as is sometimes seen in cases of widespread lichen planus—i.e., burnished papules, discrete, occurring in the position of a follicle, with a central raised point, and usually without marked spinous protrusion of the follicular contents. Except on the arms and neck the disease in this case started definitely as groups of separate horny spines protruding from the mouths of the hair follicles. This is not the case with the acuminate papules of lichen planus.

Remarks.—There has been much confusion of description and of diagnosis of cutaneous diseases which exhibit protruding spinous processes with or without surrounding congestion. The name lichen pilaris (*seu* spinulosus) has been given to the disease in which spinous processes protrude without any surrounding congestion, but the name lichen is in this connexion somewhat misleading. In the *British Journal of Dermatology* (1905) Dr. H. G. Adamson has made an exhaustive and able research into the history and literature of this subject. He points out that the spinous lesions without congestion occur in at least two recognised forms. 1. They may occur in children without any change in the general health, unaccompanied by itching, inflammation, or by any concurrent lesions of lichen planus. Dr. Adamson describes a case which had been under his care and the histology of the lesions. He found that the epithelium of the hair follicle and the papillary body showed none of the changes peculiar to lichen planus. The disease is extremely rare in this country and appears to be even more rare on the Continent and in America. In Unna's monumental work it is only briefly referred to under the name keratosis follicularis spinulosa. From the histological findings made by himself and those he was able to discover in the literature of the disease Dr. Adamson concludes that Unna's name more correctly describes the anatomy of the disease as it occurs in children. "The pathological process," he says, "is essentially a hyperkeratosis of the follicle, perifollicular inflammation is absent, or at any rate very little marked." The disease in its histology more closely resembles keratosis pilaris than lichen. In keratosis pilaris there is hyperkeratosis involving only the mouth of the hair follicle; in keratosis follicularis spinulosa the hyperkeratosis extends down into the follicle for at least two-thirds of its length. The epithelium reveals none of the changes peculiar to lichen planus. 2. Nevertheless it has been with some reason believed that this spinous lesion was in some way associated with lichen planus. In adults keratosis follicularis spinulosa has usually been associated at some time or other with papules of lichen planus. Dr. Adamson believes that Dr. J. J. Pringle was the first to notice this association and so early as 1895 to use the name lichen plano-pilaris to describe the condition. As a rule when lichen plano-pilaris is present in an adult there are also present numbers of acuminate papules of lichen planus—i.e., papules of an appearance similar to the flat papules of lichen, but acuminate in shape, having a central follicular plug and sometimes also a protruding spine. Dr. Adamson writes: "The spiny lesions in these latter cases are usually associated with the acuminate follicular lesions of lichen planus, and it is most probable that they have therefore merely an accidental association with a perifollicular disturbance ...... Such an hypothesis is made more probable by the fact that similar spines are occasionally associated with the follicular lesions of lichen scrofulosorum and miliary syphilide and also with those of pityriasis rubra pilaris."

In my case, on the contrary, the spinous lesions could not possibly be said to be secondary to the perifollicular disturbance. Both the clinical and the histological appearances pointed to the fact that the hyperkeratosis in the follicle was the primary occurrence and caused the prominent hard spine which existed for some weeks before any congested papule formed around it. The secondary feature was the papule, which presented the histological appearance of a marked hyperkeratosis follicularis spinulosa, associated with the epithelial changes also of lichen planus. In the same excised portion of skin there could be seen other follicles which showed no lichenous changes in the epithelium but only a hyperkeratosis within the follicle, and in some instances a slight perifollicular infiltration. Had the patient not been seen until June, when most of the spines had acquired their surrounding congestion, it is possible that a physician would have concluded that her disease consisted principally of acuminate papules of lichen planus in which the central spine was rather abnormally developed and that its presence was accidental and of secondary importance.

Harley-street, W.

HOSPITAL'S CHANGE OF NAME.—A special meeting of the governors of the Hertford General Infirmary was held on Oct. 22nd for the purpose of repealing some rules and adopting revised ones. The most important change made was in the name of the hospital. Mr. A. H. Smith, M.P., the chairman of the meeting, said that although the General Infirmary at Hertford had a time-honoured name it was thought advisable to alter it on two grounds. The first reason was that the word infirmary was also applied to the workhouse infirmary and often caused considerable confusion. The other reason was that an institution bearing the name of hospital had a higher status in the medical world than one which was called an infirmary. The new name decided upon was the "Hertford County Hospital."

duct, after which, the account runs, the patient at once recovered his strength and spirits, and put on weight.

I think sufficient has been said to render it evident that, notwithstanding any conception to the contrary, the

THORACIC DUCT CONSTITUTES THE CHANNEL

through which the blood is maintained in a replenished condition by the agency of food. We are faced with the recognisable fact that, concomitantly with the absorption of food, there is a concordant flow of protein, partly in the form of lymphocytes, and partly in the form of plasma constituents, into the blood.

An underrated estimate, it must be mentioned, prevails in the minds of many with respect to the number of lymphocytes present in chyle. It is not uncommon for them to be looked upon as though they were devoid of significance, and, as I have mentioned elsewhere, this is probably attributable to a faulty method of manipulative procedure. It has to be borne in mind that they become entangled in the fibrinous coagulum, and to look for them in the serous liquid is tantamount to looking for blood corpuscles in blood serum. To obtain a correct representation, it is necessary to prevent the chyle from coagulating by means of an agent like the citrate of potash. Thus treated, and examined microscopically, the lymphocytes are seen to be as closely congregated on the slide as red corpuscles on a blood film slide. Photomicrographs showing the appearance presented are given in my work on "Carbohydrate Metabolism and Diabetes."

Growth and proliferation may be regarded as the attributes of lymphocytes, and growth means the building up of protein out of more elementary material. The life-history of phagocytes is comparable to that of lymphocytes as far as incorporating power is concerned. In the case of the former, however, the material incorporated is of a grosser nature than in the case of the latter, micro-organisms and other discernible particles of matter being appropriated by them. Having played their part of converting inert matter into living protoplasm, they, lymphocytes and leucocytes alike, melt down and disappear, and in this process the protein that has been built up is set free. Lymphocytolysis and leucocytolysis are processes of admitted occurrence. Just as there are agencies leading to building up, so there are agencies, lysins, leading to breaking down.

Leucocytolysis stands upon the same footing as hæmolysis and bacteriolysis. We are in possession of established knowledge with regard to the mechanism of the two latter processes, and leucocytolysis falls into line with them. Metchnikoff has found that by the agency of the injection of lymphocytes from a lymphatic gland of a rabbit into a guinea-pig, the serum of the guinea-pig's blood acquires the power of quickly dissolving rabbit's leucocytes, no matter what the type of leucocyte present. Evidence is thus afforded that leucocytes are actually susceptible of melting down, and in the melting down, the protein that has been generated within them passes, it may be reasonably concluded, into a state of solution under the form of the

ALBUMIN, GLOBULIN, AND FIBRINOGEN

appertaining to the plasma. Seeing, it may further be said, that the proteins of the lymph and chyle are identical with those of the blood, it is not irrational to conclude that the autolysis spoken of may in part occur before the lymphocytes quit the absorbent system. In this manner the genesis of the proteins in question is traceable throughout to a kindred source.

What has been said with reference to lymphocytolysis is supported by what may be seen to take place in the lymphocytes contained in chyle collected from the receptaculum chyli and afterwards kept for a day or two. I have some stained slides, prepared in the same way as for dry blood films, representing the condition observable shortly after collection and at subsequent periods. Taken on the first day, nothing beyond the ordinary character belonging to the lymphocyte is seen. After keeping the chyle in a small bottle till the following day, and then preparing the slide, the preparation shows that a number of large, round, very faintly stained, nebular bodies had become apparent, and with a specimen that had been kept for another day, these ghost-like bodies are seen to have become larger and still more nebular, and to have scarcely taken any stain at all. They give the idea of consisting of lymphocytes in a state of dissolution, and interspersed amongst them unchanged lymphocytes are to be seen. Mr. S. G. Shattock, to whom I have submitted the slides, concurs with this view ; and if it is accepted, direct evidence is supplied of the occurrence of autolytic action outside the body. Taking it that autolysis occurs, the built-up protein cannot vanish into nothing. The only legitimate conclusion, as far as I can see, is that it becomes resolved into the proteins of the plasma.

We have now to consider what subsequently happens. The broken-down products of food digestion having been re-synthesised (assimilated) at the seat of absorption by lymphocyte growth, and the lymphocytes having been resolved by autolysis into the proteins of the blood, the transmuted food is brought within reach of the tissue cells wherein utilisation occurs. The proteins of the blood, with their large complex molecules, thus become the

PABULUM FROM WHICH THE TISSUES DRAW THEIR SUPPLY,

according to the particular need existing.

If attention is given, it will be noticed that the state of things depicted is identical with that existing in the incubating egg. Do we here find the growing tissues of the chick drawing their supply from a collection of small molecular, broken-down products, as, it has been suggested, the food is converted into for the tissue supply of the developed animal? No, the material provided by Nature for tissue growth and service in connexion with incubation is comparable in character to the protein constituents of the blood.

Having followed the food to the protein constituents of the blood, the point now before us is to inquire into what next occurs. Utilisation in growth, in maintenance, and in energy production are the ends to be reached. For this to be carried out, incorporation with the bioplasmic molecule is necessary. In what precise way, it may be asked, does this incorporation take place? Do the protein molecules as such become linked on to the living cell molecules, or does any preliminary breaking-down action occur?

In the case of the vegetable kingdom, distinct evidence is before us of the occurrence of breaking down by enzyme action preparatory to utilisation. Take, for example, what is observable in the germinating tuber and seed. The store of starch lying within the range of influence of the germinating material becomes broken down into sugar before it is made use of. Again, in connexion with the operations taking place in the life-history of yeast, we know that a sugar, saccharose, which is not susceptible of being turned to account whilst existing as such, is rendered serviceable by the instrumentality of an enzyme, invertase, produced by the yeast, which splits the saccharose up into dextrose and levulose.

The side-chain theory bearing on immunity, &c., also brings in the taking-on of nutrient matter by the bioplasmic molecule, and something allied, as will be later seen, to what has just been mentioned with regard to molecular breaking down, is comprehended in the theory. The theory stands in conformity with the accepted doctrine applying to the dominating factors regulating ordinary chemical action. Affinity and suitable molecular configuration are conjointly at the foundation of chemical union. Let it be supposed that atoms have been joined by a strong bond of union into a group classified as a ring or nucleus. To any member of the group having a free or unsaturated bond, suitable atoms or molecules can be

LINKED ON IN THE FORM OF A SIDE-CHAIN,

which can not only be subsequently removed, but likewise replaced by another, without disturbing the integrity of the original group.

Now, a bioplasmic molecule is viewed as constituting a large and complex molecule, consisting of a nucleus or functioning centre, around which are innumerable arms or side-chains equipped with endings capable of taking on molecules or groups of molecules that are similarly provided with suitably adapted side-chain endings. There must be adaptability between the ending that takes on and that which is taken on, and it is conjectured that an infinite variety of endings exists, so as to make provision for the attachment of the diversity of groupings that become affixed. When linked on, a mutual interchange of influence occurs between the centre and the side-chain groups. At the same time, however, the latter can seemingly be used up or worked off, whilst the former is left intact. It is in this molecular complex that the various chemical changes occur which give of suitable capacity, and the bisulphite as it left the tank to flow into the storage or service reservoir. Assuming that on the large scale the same results can be obtained as in the laboratory, and there appears to be no reason why such should not be the case, the adoption of such a method of water purification may result in an enormous saving in capital expenditure and very greatly reduce the risk of water-borne epidemics.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HERPES ZOSTER FRONTALIS ASSOCIATED WITH GLAUCOMA.

By A. A. Bradburne, F.R.C.S. Edin.

THE chief feature which is generally relied upon to distinguish glaucoma from iritis is the size of the pupil. A recently published work says: "In glaucoma there is increased tension. In iritis the tension is usually normal, but for those who cannot rely on their estimation of tension there are other valuable points on which to base the diagnosis ...... it is the pupil which will in most cases give us the necessary clue. In glaucoma the pupil is dilated—often pear-shaped. In iritis the pupil is contracted." Glaucoma can, however, be associated with a *contracted* pupil when the iris is fastened down to the lens capsule behind, thus shutting off the posterior from the anterior chamber of the eye. The recognition of such an atypical condition is easy if one be careful to note the plane of the iris which will be either that of the underlying lens, to which it is completely attached, or else ballooned out (iris bombé) by pressure of the aqueous behind it, the edge of the pupil by its attachment to the lens giving the pupil a characteristically cupped appearance.

The interesting feature of this case is the fact that although there was undoubted increase of ocular pressure the pupil was *not dilated*; such a combination of symptoms is quite compatible with an iritis in which the plus tension is due to congestion and swelling of the iris and increased viscosity of the aqueous fluid. What made the case still simulate iritis was the marked swelling of the upper lid and the accompanying intense conjunctival injection; in fact, a superficial preliminary examination presented a typical picture of iritis, and had not the eye been most carefully scrutinised the instillation of a mydriatic would have seemed urgently necessary. On account of the œdema of the upper lid making recognition of increased intra-ocular tension difficult, this feature, contra-indicating the use of a pupil-dilating agent, could easily have been overlooked. Had, therefore, a mydriatic been instilled, as symptoms seemed to call for, a most unfortunate result would assuredly have followed. The cultivation of a faculty for observing minutiæ of detail is the secret of making correct diagnosis in eye affections. Now, not only had Dr. Weldon C. Carter correctly estimated the presence of increased tension, but had further noted that there was an *absence of the rose-red ring of ciliary injection* around the corneo-scleral margin which is always present in inflammation of the iris and ciliary body. He had also noted that the cornea was clear and bright and the iris markings were not obscured, and the pupil was fairly mobile. It was plainly evident, then, that a combination of signs was present which were contradictory in character, and for this reason desired my opinion to help to solve the problem.

The patient was a single woman, aged 53 years, the subject of rheumatoid arthritis attacking mainly the ankle- and shoulder-joints. Her skin was hot and dry, the tongue was furred, and the left side of the face and head was dusky-red and congested. For three days she had been suffering from a most intense pain radiating from the left eye over the forehead, the left side of the nose, and face. As already stated, the upper lid was considerably swollen and in a condition of partial ptosis. The conjunctiva lining the eyelids was congested and to a certain extent the ocular portion as well. Some thin transparent mucus was present as well as profuse lacrymation, and the eye was very sensitive to light and even to the slightest touch. The pupil was four millimetres in diameter, not perfectly circular, and moved under light stimulus. The colour and markings of the iris were unaltered, the cornea reflected brightly, and the media were perfectly clear. The anterior chamber was shallow, and gentle careful palpation revealed increased tension. Some recession of the optic nerve head could be seen, but was not in the condition associated with the later stages of glaucoma. The temperature and pulse were normal. There was another symptom which was out of all proportion to the objective signs, and this was the severity of the pain, its intensity being such as is usually associated with an attack of *acute* glaucoma. The clearness of the cornea, the absence of dusky venous engorgement of the ocular conjunctiva, as well as the absence of extreme hardness of the eyeball negatived a diagnosis of acute glaucoma. Against the case being iritis was the mobility of the pupil, the clearness of the texture of the iris, and the absence of ciliary injection. It was evident, then, that the increase of tension was only a secondary manifestation of a cause which had not so far revealed itself. When the patient first consulted Dr. Carter complaining of the severe pain in and around the orbit, he considered the probability of herpes zoster and kept this probability in view until the development of the eye affection led him to weigh the possibility that the cause might arise from the eye itself. 24 hours after my seeing the patient a crop of vesicles developed on the forehead, which at once revealed the true nature of the affection.

During the course of the disease a change came over the condition of the eye which entailed the necessity for a second consultation. This time the eye was found to be free from pain, photophobia, and sensitiveness to touch. The tension was subnormal, the anterior chamber deep, the pupil semi-dilated and immobile, and the texture of the iris was partially obscured. The explanation of these altered appearances was simple. There was evidently a thin viscid but transparent mucoid secretion present in the aqueous which accounted for the loss of transparency of the media and obscured the texture of the iris. The minus tension could be attributed to the defective secretory function of the ciliary body due to the paralysing effect of the affection on the long ciliary nerves. These symptoms indicated the urgent necessity of preventing adhesions forming between the iris and the lens capsule which the viscid mucus in the anterior chamber of the eye tended to produce. The use therefore of a mydriatic was obviously required now as much as it was contra-indicated in the early condition and under this treatment the eye rapidly recovered.

The case is considered worthy of record if only on account of the manner in which it indicates the importance of observing the minutest details and correctly gauging their true indications and how it is possible for the so-called classical symptoms at times to become absolutely misleading.

Southport.

A CASE OF INTERNAL HÆMORRHAGE CONSEQUENT UPON TUBAL GESTATION WITH UNUSUALLY EARLY SYMPTOMS.

By James Oliver, M.D. Edin., F.R.S. Edin.

PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE, W.

THE patient, aged 27 years and married six years, consulted me on Sept. 30th last. She had had one child but no miscarriage; the child was born five years ago. When I saw her she had had during the previous three weeks a constant hæmorrhagic discharge from the vagina. When this hæmorrhagic discharge made its appearance the patient affirmed that it was the correct time for her being unwell and that she had menstruated as usual four weeks previously. Five weeks before coming under my observation—about two weeks after the last normal menstrual period—she was suddenly seized with severe pain in the right iliac region. This attack lasted altogether about one hour; it was not attended or followed by any hæmorrhagic discharge from the vagina. 14 days after the first attack the patient experienced a second and similar attack of pain and on this occasion the external hæmorrhage made its appearance. During the three weeks that there has been external hæmorrhage there have been three similar attacks of pain; the last attack was on the day preceding her

THE "EFFECTIVE PERIODS" OF TYPHOID "CARRIERS." *

By D. S. DAVIES, M.D. Lond., D.P.H. Cantab.,
MEDICAL OFFICER OF HEALTH OF THE CITY OF BRISTOL;

AND

I. WALKER HALL, M.D. Vict.,
PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, BRISTOL, AND
PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

In a previous communication[1] we intimated our intention to continue observations upon the typhoid "carrier" whose case we described. Since then we have traced another outbreak to a typhoid carrier and have prosecuted inquiries from several standpoints in order to determine certain factors associated with the transmission of the organism. One of these is connected with the "effective" periods of the carrier, and although the facts already ascertained are limited to few cases we consider that their publication may call further attention to the whole question of typhoid carriers and so indirectly furnish additional material for investigation.

It may be remembered that Mrs. H., the subject of our earlier paper, was found to be the cause of three outbreaks of enteric fever in institutions where she was acting as cook. In November, 1907, she was proved to be a typhoid carrier, and her removal from any contact with food resulted in the disappearance of enteric fever from the institution where she was working. From that time we have had her under strict control, her fæces have been examined frequently, and her clinical condition has been duly noted. In addition to the bacteriological examination of the fæces attention has been paid to the character of the stools, and in Chart 1 these are described as formed, disturbed, diarrhœic. There appears to be some relationship between the unformed stools and the presence of bacillus typhosus in the fæces.

On Dec. 20th, 1907, typhoid bacilli were obtained from the fæces. Negative results were then the rule until the following April 14th, when a luxuriant growth of bacillus typhosus appeared on the plates. Further daily examinations showed the organisms to be present on May 11th, 21st, and 29th, and on June 10th. The urine did not contain the bacillus typhosus. About May 21st Mrs. H. fell ill. The pulse-rate was 120, the temperature was 100° F., and she presented a "typhoid" appearance. Chart 1 gives the temperature and pulse curves. Differential blood counts showed an increase of mononuclear cells—35 to 50 per cent. Unfortunately, at the time it was impossible to arrange for a count of the total number of white cells. Her blood gave a good and prompt agglutination, 1 in 25, but was negative in higher dilutions. With a view to the consideration of other causes the blood was examined bacteriologically. No organisms were present. Her opsonic index was then determined for staphylococci, streptococci, bacillus coli communis, and bacillus typhosus. This was carried out by the opsonic assistant at the Bristol Royal Infirmary, Dr. J. M. H. Munro, to whom we are much indebted. The result was as follows: staphylococci, 0·99; streptococci, 1·07; bacillus coli communis, 1·2; and bacillus typhosus, 1·7. Minute examinations of the fæces failed to reveal any gall-stone, and there were no clinical signs of biliary obstruction.[3] We concluded that the patient was probably suffering from a self-inflicted attack of enteric fever, although we recognise that the attack may have been a cholecystitis, or some form of enteritis. The associated presence of bacillus typhosus in the stools led us to regard it as probably a typhoid enteritis. The duration of the illness was about three weeks.

Since this "carrier" was removed from her position in the dairy in November last she has lived in a separate block with some typhoid convalescents. In July, 1908, a woman with whom she had been daily closely associated for some months was attacked with typhoid fever. It was found that after the carrier had eaten as much as she could of her lunch she handed the remainder to her companion. This suggested a probable means of infection and an endeavour was made to find bacilli on the hands of the carrier after defæcation and before ablution. The investigation is still in progress. Up to the present only cocci, moulds, and motile bacilli have been isolated. No bacillus coli communis or typhoid bacilli have been found. The carrier, however, now endeavours to prevent any soiling of the skin after defæcation, &c. It may be possible to obtain positive results from other carriers before they alter their usual habits.

Second carrier case.—Before considering the question of "periodicity" and "effective periods" we may perhaps mention the details of another case we have met with. In September, 1907, J. H—n had enteric fever and died. His wife, who had nursed him prior to his removal to hospital, had a slight attack of enteric fever in October–November, 1907. After recovery she continued her household duties. All went well until June 6th when her four children were simultaneously attacked with enteric fever. In the absence of any other cause the woman herself fell under suspicion, and it was found that her blood agglutinated bacillus typhosus 1 in 200. On several subsequent occasions the Widal reaction has been obtained in similar dilutions. The fæces are being repeatedly examined from the standpoint of "periodicity."

The May period of infectivity.—We have already pointed out that Mrs. H. was responsible for three outbreaks. In May, 1904, she was at a home for girls, Brislington, where 25 cases of typhoid fever and two deaths occurred. In May, 1905, she was at a girls' home in Clifton, where typhoid fever broke out. In May, 1907, the second and larger group of Brentry cases commenced. At all these places she was present for some time before any typhoid fever appeared. January, February, and March were the months during which she was "ineffective." This year (1908) her isolation has prevented any wide transmission of the organisms, but, curiously enough, she appears to have infected herself about the same time of the year—viz., May—and a single fellow inmate in July. The fæces examined in January, February, and March did not contain typhoid bacilli. In Chart 2 we show these periods. The time during which she was in a position to infect food is shown by a thin line and it will be seen that it was not until May that she became "effective," while, under favourable circumstances, her effectiveness then continued to the end of the year. In the second case, Mrs. H—n, it is again the food preparer who acts as the typhoid carrier. After recovery from her November attack she continued her household duties and everything went well until the end of May or June, when the whole family, except herself and one son, were infected with the typhoid bacillus.

We may now summarise shortly some of the carrier cases already reported.

Kayser's and Klinger's carrier cases.—

Case 1.—Mrs. E., a confectioner, had enteric fever in 1894. Nearly all her assistants suffered from indigestion and diarrhœa shortly after entering her service. On May 20th, 1904, her assistant, L. R., had enteric fever. On May 24th typhoid bacilli were found in the stools of Mrs. E. On August 8th, 1904, her lodger, J. W., was attacked with enteric fever.

Case 2.—Mrs. M., a secondhand clothes dealer, had enteric fever in 1874. In 1899 she had an attack of severe biliary colic. On Nov. 24th, 1904, she was found to be a carrier. On May 20th, 1904, her son-in-law, who lived with her, fell ill with enteric fever. On Nov. 17th, 1904, her lodger, A. B., was similarly attacked.

Case 3.—Mrs. Z., a tailor's wife. In January, 1905, a new servant came into the house. Three weeks later the maid developed enteric fever.

Case 4.—Mrs. L. Her servant was attacked with enteric fever in April, 1905.

Case 5.—Miss N. had enteric fever in 1881. Her servant showed signs of enteric fever on June 28th, 1905.

Case 6.—Mrs. S. had enteric fever in 1877. In August, 1900, she had an attack of biliary colic. In September her children developed typhoid fever.

Soper's case.—The details of this case have been so carefully and fully worked out by Dr. Soper that we may safely assume that during the intervals of the dates mentioned the carrier was "ineffective." In June, 1902, the carrier, who was a cook, joined a family three weeks before the summer exodus. At the end of this time enteric fever appeared. In October, 1903, she entered the service of another family. Nine months later—viz., June, 1904—the family went for the summer holiday, taking the cook with it was formed and also as a general protoplasmic poison. In order to study the healing of gastrotoxic ulcers the ulcers were produced by local injection of the serum into the stomach wall, as by that means an ulcer could be produced without toxic symptoms. It was found that such ulcers healed completely in normal animals in from 14 to 28 days. Repeated injection of the serum did not lead to chronic ulceration, as the animals became immune to it. The position of the ulcer in the stomach did not affect the healing. Hyperacidity of the gastric contents and diminished acidity did not retard the healing and so produce a chronic ulcer.

* The superior figures refer to the bibliography at the end.

CLINICAL SECTION.

Exhibition of Cases.

A Meeting of this section was held on Nov. 13th, Sir Thomas Barlow, the President, being in the chair.

The President in a sympathetic reference to the death of Dr. J. G. Glover said that all who knew him would unite in an expression of sincere regret at the loss which the section had suffered by his death.

Dr. J. F. Gordon Dill showed a case of Pernicious Anæmia treated by Lactobacillin. The patient was a man, aged 34 years, who had diarrhœa in South Africa in 1901. Since then he had worked at house painting and plastering, until July, 1905, when he was suddenly seized with violent abdominal pain and diarrhœa; persistent vomiting appeared three days later, and these severe symptoms lasted seven weeks. During 1906 and the early months of 1907 he never lost the vomiting or diarrhœa, the motions averaging eight a day. Gradually dyspnœa and palpitation came on. He was admitted to hospital on Oct. 10th, 1907, with tenderness over the colon and extreme anæmia. The stools contained enormous numbers of streptococcus fæcalis and bacillus enteritidis (Gärtner). A blood count on Oct. 12th showed: red blood corpuscles, 1,468,000; leucocytes, 3500 (polymorphonuclears 48 per cent., lymphocytes 52 per cent.); hæmoglobin, 32 per cent.; and colour index, 1·1. Some of the red cells showed punctate basophilia, and in later examinations many nucleated red cells were seen, megaloblasts being noted in three out of 20 examinations. For four months (October, 1907, to January, 1908) he was treated with arsenic and intestinal antiseptics; he also had vaccines made from streptococci from the bowel and from the sore tongue. After this, on Jan. 23rd, 1908, the red cells were 1,568,000, leucocytes 3000, hæmoglobin 60, and colour index 1·8. He was put on lactobacillin from Jan. 14th to March 2nd; on March 19th the red cells were 1,725,000, the colour index 1·3, and leucocytes 1750. On April 3rd, after not having had any lactobacillin for a month, the red cells had fallen to 1,392,000 and colour index 1; he was put on lactobacillin. On April 23rd the red cells were 1,000,000 and colour index 1·8. From this date the blood condition gradually improved until Sept. 30th, when the red count was 4,800,000, leucocytes 6400, hæmoglobin 100 per cent., colour index 1·04, and no nucleated red cells. Except for the month of July he had been on lactobacillin since April 4th.—Dr. George Herschell pointed out the importance of being sure that the lactic ferment used was active, as the market was sometimes flooded with preparations, some good, some useless, and some probably injurious. A tablet should conform to the following tests. It should be pure white in colour, should disintegrate within three or four minutes when placed in water, it should be odourless, neutral in reaction, and when cultivated on Cohendy's serum of milk should give a culture of the Bulgaria bacillus with perhaps one other organism added to improve the flavour of the milk curdled by it.—Dr. Dill, replying to the President, said that there were not any notes about urobilin in the case; and in answer to Mr. G. Eastes he said that the diarrhœa had been ameliorated. He admitted that many of the tablets on the market were inert, but with some he had had remarkable results in intestinal antisepsis.

Dr. F. Parkes Weber showed a case of Congenital Heart Disease with extreme Secondary Polycythæmia and Orthostatic Albuminuria. The patient was a man, aged 22 years, who was undersized and did not look more than 15 or 16 years old. There was great cyanosis of the lips, tongue, nose, ears, hands, and feet. His tongue and lips were bluish-black in colour. There was great clubbing of the fingers and toes. A blood examination (capillary blood from finger) on Oct. 18th, 1908, showed that the blood was very dark in colour, hæmoglobin (by Haldane's method) 160 per cent., red cells 10,300,000 per cubic millimetre, and white cells 7000. A differential count of 500 white cells made by Dr. A. E. Boycott gave lymphocytes, 17·2 per cent.; intermediate, 5·4 per cent.; large hyaline, 2·2 per cent.; polymorphonuclear, 72·2 per cent.; eosinophile, 2·0 per cent.; and mast cells, 1·0 per cent. The red cells appeared quite normal though the colour index was low. The congenital malformation in the present case seemed to be patency of the interventricular septum.

Dr. C. H. Miller showed a case of Polycythæmia. The patient was a man, aged 44 years, who in April, 1906, began to suffer from shortness of breath, palpitation, giddiness, and lately bad headaches and epistaxis. There were general cyanosis and great clubbing of the fingers and toes. A blood count gave the following result: red cells, 12,010,000 per cubic millimetre; white cells, 10,000; hæmoglobin, 140 per cent.; blood volume, $10\frac{3}{4}$ litres; oxygen capacity, 3·375 cubic centimetres (taken by Dr. Boycott). Improvement occurred when treated by rest, warmth, venesection, saline infusions, iodides, and arsenic.

Dr. Miller also showed a case of Splenomegalic Polycythæmia. The patient was a man aged 39 years. His illness began at Christmas, 1906, with shortness of breath, pains in the chest and legs, and occasional bleeding from the gums. The legs were swollen. There was not any clubbing but there was great cyanosis of the lips, face, fingers, and toes. The spleen was enlarged and hard. There were 11,300,000 red blood corpuscles per cubic millimetre and 15,300 leucocytes per cubic millimetre; a differential count gave polymorphonuclears 81 per cent., lymphocytes 12 per cent., others 7 per cent.; no abnormal cells were found.

Dr. H. Theodore Thompson showed a case of Polycythæmia. The patient during the last three years had been gradually becoming blue; he complained of headache and weakness. He had had syphilis many years ago and there was a scar of old gumma of the manubrium. The spleen was much enlarged and there was intense cyanosis. The red count varied from 10,000,000 to 13,000,000 per cubic millimetre; hæmoglobin, 140 per cent. The arterial, venous, and capillary blood pressures were normal. Treatment by iodides and oxygen inhalations was without any effect. The patient was now being treated with the x rays to the bones and spleen.—Dr. H. D. Rolleston suggested in these cases treatment with serum obtained from an animal in which a cytolytic action had been induced so as to affect the red marrow of the bones.—Dr. Weber said that bleeding had been tried with doubtful results in some cases, and the President considered that it was a useful method of treatment when cerebral manifestations were present.

Dr. James S. Collier showed a case of Chronic Purpura. The patient in July last, when suffering from septic gingivitis, developed a whitlow. The temperature rose to 104° F. and remained high for a week, and during this pyrexial period the most profuse purpura appeared, the body being almost universally black. Examination of the blood showed the presence of a few cocci only. The patient's general condition rapidly improved; he now felt in good health. Purpura had occurred almost daily since the beginning of his illness despite every kind of treatment, and frequently he was troubled with an urticarial rash, which was at once benefited by the administration of calcium chloride. The chronic œdema of the forehead suggested some septic focus in the nasal passages, but repeated examination had failed to reveal anything.

Mr. Raymond Johnson showed a case of Fracture of the Patella resulting from syphilitic osteitis.

Mr. A. Carless showed a case of Extensive Fracture of the Pelvis with recovery. The patient was a boy, aged 17 years, over whose sacrum a heavy van had passed.

Dr. F. E. Fenton showed a case of von Recklinghausen's Disease in a woman, aged 52 years, in which about 40 of the largest tumours (which varied from the size of a pea to that of a walnut or even an egg) had been excised, the pedunculated ones being ligatured. Fibrolysin had been injected hypodermically for the last ten weeks, with the result that the size of the tumours had diminished and their consistence had been rendered soft.—Dr. Thompson also showed a case of the same disease.—Dr. Rolleston said that a case of von Recklinghausen's disease should show neuro-fibromata, molluscous tumours, and pigmentation.—Dr. Weber thought that the name should be given to a case with any of the

THE "EFFECTIVE PERIODS" OF TYPHOID "CARRIERS."*

By D. S. DAVIES, M.D. Lond., D.P.H. Cantab.,
MEDICAL OFFICER OF HEALTH OF THE CITY OF BRISTOL;

AND

I. WALKER HALL, M.D. Vict.,
PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, BRISTOL, AND PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

In a previous communication[1] we intimated our intention to continue observations upon the typhoid "carrier" whose case we described. Since then we have traced another outbreak to a typhoid carrier and have prosecuted inquiries from several standpoints in order to determine certain factors associated with the transmission of the organism. One of these is connected with the "effective" periods of the carrier, and although the facts already ascertained are limited to few cases we consider that their publication may call further attention to the whole question of typhoid carriers and so indirectly furnish additional material for investigation.

It may be remembered that Mrs. H., the subject of our earlier paper, was found to be the cause of three outbreaks of enteric fever in institutions where she was acting as cook. In November, 1907, she was proved to be a typhoid carrier, and her removal from any contact with food resulted in the disappearance of enteric fever from the institution where she was working. From that time we have had her under strict control, her fæces have been examined frequently, and her clinical condition has been duly noted. In addition to the bacteriological examination of the fæces attention has been paid to the character of the stools, and in Chart 1 these are described as formed, disturbed, diarrhœic, There appears to be some relationship between the unformed stools and the presence of bacillus typhosus in the fæces.

On Dec. 20th, 1907, typhoid bacilli were obtained from the fæces. Negative results were then the rule until the following April 14th, when a luxuriant growth of bacillus typhosus appeared on the plates. Further daily examinations showed the organisms to be present on May 11th, 21st, and 29th, and on June 10th. The urine did not contain the bacillus typhosus. About May 21st Mrs. H. fell ill. The pulse-rate was 120, the temperature was 100° F., and she presented a "typhoid" appearance. Chart 1 gives the temperature and pulse curves. Differential blood counts showed an increase of mononuclear cells—35 to 50 per cent. Unfortunately, at the time it was impossible to arrange for a count of the total number of white cells. Her blood gave a good and prompt agglutination, 1 in 25, but was negative in higher dilutions. With a view to the consideration of other causes the blood was examined bacteriologically. No organisms were present. Her opsonic index was then determined for staphylococci, streptococci, bacillus coli communis, and bacillus typhosus. This was carried out by the opsonic assistant at the Bristol Royal Infirmary, Dr. J. M. H. Munro, to whom we are much indebted. The result was as follows: staphylococci, 0·99; streptococci, 1·07; bacillus coli communis, 1·2; and bacillus typhosus, 1·7. Minute examinations of the fæces failed to reveal any gall-stone, and there were no clinical signs of biliary obstruction.[3] We concluded that the patient was probably suffering from a self-inflicted attack of enteric fever, although we recognise that the attack may have been a cholecystitis, or some form of enteritis. The associated presence of bacillus typhosus in the stools led us to regard it as probably a typhoid enteritis. The duration of the illness was about three weeks.

Since this "carrier" was removed from her position in the dairy in November last she has lived in a separate block with some typhoid convalescents. In July, 1908, a woman with whom she had been daily closely associated for some months was attacked with typhoid fever. It was found that after the carrier had eaten as much as she could of her lunch she handed the remainder to her companion. This suggested a probable means of infection and an endeavour was made to find bacilli on the hands of the carrier after defæcation and before ablution. The investigation is still in progress. Up to the present only cocci, moulds, and motile bacilli have been isolated. No bacillus coli communis or typhoid bacilli have been found. The carrier, however, now endeavours to prevent any soiling of the skin after defæcation, &c. It may be possible to obtain positive results from other carriers before they alter their usual habits.

Second carrier case.—Before considering the question of "periodicity" and "effective periods" we may perhaps mention the details of another case we have met with. In September, 1907, J. H—n had enteric fever and died His wife, who had nursed him prior to his removal to hospital, had a slight attack of enteric fever in October-November, 1907. After recovery she continued her household duties. All went well until June 6th when her four children were simultaneously attacked with enteric fever. In the absence of any other cause the woman herself fell under suspicion, and it was found that her blood agglutinated bacillus typhosus 1 in 200. On several subsequent occasions the Widal reaction has been obtained in similar dilutions. The fæces are being repeatedly examined from the standpoint of "periodicity."

The May period of infectivity.—We have already pointed out that Mrs. H. was responsible for three outbreaks. In May, 1904, she was at a home for girls, Brislington, where 25 cases of typhoid fever and two deaths occurred. In May, 1905, she was at a girls' home in Clifton, where typhoid fever broke out. In May, 1907, the second and larger group of Brentry cases commenced. At all these places she was present for some time before any typhoid fever appeared. January, February, and March were the months during which she was "ineffective." This year (1908) her isolation has prevented any wide transmission of the organisms, but, curiously enough, she appears to have infected herself about the same time of the year—viz., May—and a single fellow inmate in July. The fæces examined in January, February, and March did not contain typhoid bacilli. In Chart 2 we show these periods. The time during which she was in a position to infect food is shown by a thin line and it will be seen that it was not until May that she became "effective," while, under favourable circumstances, her effectiveness then continued to the end of the year. In the second case, Mrs. H—n, it is again the food preparer who acts as the typhoid carrier. After recovery from her November attack she continued her household duties and everything went well until the end of May or June, when the whole family, except herself and one son, were infected with the typhoid bacillus.

We may now summarise shortly some of the carrier cases already reported.

Kayser's and Klinger's carrier cases.—

Case 1—Mrs. E., a confectioner, had enteric fever in 1894. Nearly all her assistants suffered from indigestion and diarrhœa shortly after entering her service. On May 20th, 1904, her assistant, L. R., had enteric fever. On May 24th typhoid bacilli were found in the stools of Mrs. E. On August 8th, 1904, her lodger, J. W., was attacked with enteric fever.

Case 2.—Mrs. M., a secondhand clothes dealer, had enteric fever in 1874. In 1899 she had an attack of severe biliary colic. On Nov. 24th, 1904, she was found to be a carrier. On May 20th, 1904, her son-in-law, who lived with her, fell ill with enteric fever. On Nov. 17th, 1904, her lodger, A. B., was similarly attacked.

Case 3.—Mrs. Z., a tailor's wife. In January, 1905, a new servant came into the house. Three weeks later the maid developed enteric fever.

Case 4.—Mrs. L. Her servant was attacked with enteric fever in April, 1905.

Case 5.—Miss N. had enteric fever in 1881. Her servant showed signs of enteric fever on June 28th, 1905.

Case 6.—Mrs. S. had enteric fever in 1877. In August, 1900, she had an attack of biliary colic. In September her children developed typhoid fever.

Soper's case.—The details of this case have been so carefully and fully worked out by Dr. Soper that we may safely assume that during the intervals of the dates mentioned the carrier was "ineffective." In June, 1902, the carrier, who was a cook, joined a family three weeks before the summer exodus. At the end of this time enteric fever appeared. In October, 1903, she entered the service of another family. Nine months later—viz., June, 1904—the family went for the summer holiday, taking the cook with date. It might also be that the method of displacement of the sac rather than ligature of the sac (before its removal) had the effect of eliminating that cause. The additional sutures placed by some surgeons to close the space above the cord might also effect the same object. The effect of undue strain was undoubtedly considerable. How much trouble might arise from the vomiting which followed the use of anæsthetics it was not possible to estimate. At the end of a fortnight the patient could safely go about again and walk from place to place in moderation, but the muscular exertion which he underwent should be gradually increased and at no time violent. In most of the cases which had been operated on by himself, as well as in those which had been subjected to operation by other surgeons, there was an excess of scar tissue in the inguinal canal which in some instances matted the parts together in a manner which made it difficult to differentiate the structures. In three instances the posterior wall was so firmly fixed to the cord that Foster's operation was done—that is, the cord was not disturbed but the internal oblique was sutured to Poupart's ligament over it after removal of the sac, and the canal closed in the usual manner. As regards the condition of the sac, it was frequently difficult to separate, being thickened and adherent to the cord, but in every instance save one it was ultimately separated and ligatured before removal. The exception was made in a case of direct hernia where the sac presented no definite neck, and was invaginated without the removal of any part of it. In three the hernia had become irreducible, omentum being adherent to the inside of the sac. In two of these omentum required to be excised.—Mr. G. R. TURNER said that in operating for hernia he never let age stand in his way unless the age of the patient was such as to make the giving of the anæsthetic a danger.—Mr. A. E. BARKER pointed out the advantage of using silver wire net-work to support the parts when dealing with very indolent tissues.—The PRESIDENT commented on the diminution in the frequency of recurrence and Mr. BATTLE said he was unwilling to use silver-wire netting because he objected to put such a foreign body into the inguinal region where movement was so well marked.

---

* The superior figures refer to the bibliography at the end.

Mr. V. WARREN LOW read a report on two cases of Hæmorrhage into the Testicle. In the first case the patient was a youth, aged 19 years, who went to the out-patient department of St. Mary's Hospital on April 19th, 1907. He complained that two days previously his left testicle had become swollen and painful. The case was considered to be one of tuberculous disease of the testicle and epididymis, and the removal of the organ was advised. That was carried out on May 7th. On section the body of the testis was firm and dry and had a uniform grey colour. In the region of the rete testis were several small ill-defined hæmorrhages. In the epididymis and cord were dilated blood-vessels but no hæmorrhages were here present and no indication of torsion of the cord. The second case was that of a young man, aged 21 years, who was sent to him in May, 1907, with the history that while moving he was seized in his left testicle with a sudden violent pain, of such severity as to cause him to lie on the floor. Mr. Low saw him on May 11th, about four weeks after the attack. The left testicle was then enlarged and slightly, but not excessively, tender. Mr. Low came to the conclusion that the case was one of tuberculous epididymitis and the organ was removed. On examination the body of the testis was firm and had a caseous appearance throughout and the epididymis and cord contained dilated blood-vessels. In the rete testis were thrombosed veins and blood clot almost completely discoloured. In each case there had been a sudden hæmorrhage into the substance of the testicle, with consequent destruction of its glandular elements, and in neither case was the cause of that hæmorrhage at all obvious. Sudden hæmorrhage into the testicle, when it was not an accompaniment of a new growth, was almost invariably the result of torsion, either of the cord or of the "mesentery" of the testicle. But in the cases which he had brought forward no evidence of such a twist could be discovered, and what was, perhaps, of more importance, the testicle and epididymis were normally attached to the back of the tunica vaginalis.—Mr. EDRED M. CORNER said that the trend of modern opinion in regard to these cases was to regard with doubt the ancient diagnoses of gangrene, spontaneous necrosis, thrombosis, &c., and it was now suggested that these cases were due to torsion of the cord, but he did not think that it accounted for all these cases.—Mr. T. H. KELLOCK said that it was important to know how high up the cord the hæmorrhage went.—Mr. BARKER narrated similar cases where he did not operate, and the PRESIDENT pointed out that the question arose where a hæmorrhage began, after which Mr. LOW replied.

OPHTHALMOLOGICAL SOCIETY.

Orbital Abscess following Retinal Embolism.—Nodular Opacity of the Cornea in Three Generations.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 12th, Mr. R. MARCUS GUNN, the President, being in the chair.

Dr. A. L. WHITEHEAD read a paper entitled "A Case of Orbital Abscess following Retinal Embolism." The patient, a woman, aged 42 years, after an illness of ten days' duration, with elevation of temperature and pain in the right shoulder, suddenly lost the sight in one eye. This eye subsequently became acutely inflamed and proptosed and an orbital abscess formed. The abscess was opened and the eye was excised; pus was found to be exuding through a necrosed area of sclerotic. The axillary vein subsequently became thrombosed and suppurated. The absence of any primary focus of suppuration and the presence of a systolic mitral bruit rendered the diagnosis of infective retinal embolism secondary to endarteritis probable.—Mr. J. H. PARSONS, in commenting on the case, drew attention to the importance of a bacteriological examination of the blood in such cases, and showed, by narrating cases, that the behaviour of the case varied greatly according to the particular organism responsible. There was also a strong selective factor as regards site in the case of various organisms.—Mr. ANGUS MACNAB pointed out that in many cases where the abscess contents were afterwards found to be sterile the pneumococcus was the organism responsible.—Dr. WHITEHEAD replied. The pus from the eye was sterile, while that from the abscess contained some diplococci.

Mr. HERBERT H. FOLKER read a paper on Nodular Opacity of the Cornea in Three Generations. 25 members of this family had been examined and the opacity was found in nine of them. In the first and second generations five were examined and nodular opacity was present in three members. In these cases, in addition to the opacities, fine lattice-like lines were found in conjunction with them. This latter condition was absent in members of the third generation. The nodular opacities were fewer in number and less in density in the younger members. In all the cases the opacities appeared to be situated in the anterior layers of the substantia propria, the epithelial layer not being involved. No signs of syphilis or history of rheumatism were present in any of the cases. He was indebted to Mr. George A. Carter of Tunstall, who first sent an affected member of the family to him and who had taken great pains in assisting to trace the various members of the family.—The PRESIDENT remarked on the large amount of work done by the society recently on the question of heredity. In only two cases had he seen nodular opacities of the cornea associated with raising of the epithelium.—Mr. G. COATS described the histology of a case which he had examined.—Mr. MACNAB remarked on the advantage which had accrued when he shaved the cornea.—Mr. J. HERBERT FISHER drew attention to some notes of a case of nodular keratitis which he showed three years ago.—Mr. W. T. HOLMES SPICER also described cases, and said that he had scraped from them material which was found to be hyaline with calcareous deposits in it.—Mr. R. W. DOYNE, Mr. SYDNEY STEPHENSON, Mr. N. BISHOP HARMAN, Mr. E. TREACHER COLLINS, Dr. W. S. INMAN, Major R. H. ELLIOT, I.M.S., Mr. E. NETTLESHIP, and others also joined in the discussion, and Mr. FOLKER replied.

The following card specimens were shown:—

Mr. R. R. JAMES: Birth Injury of Cornea.

Dr. WHITEHEAD: Specimen from a case of Irido-cyclitis followed by Perforation of the Sclerotic and Orbital Abscess.

Mr. STEPHENSON: Crateriform Hole in the Optic Disc.

Dr. RAYNER D. BATTEN: Acute Optic Neuritis in one Eye with Macular Changes in the other.

Mr. LESLIE J. PATON: Cataract developing subsequently to Exposure to the X Rays.

CHART 3.—Periodicity.

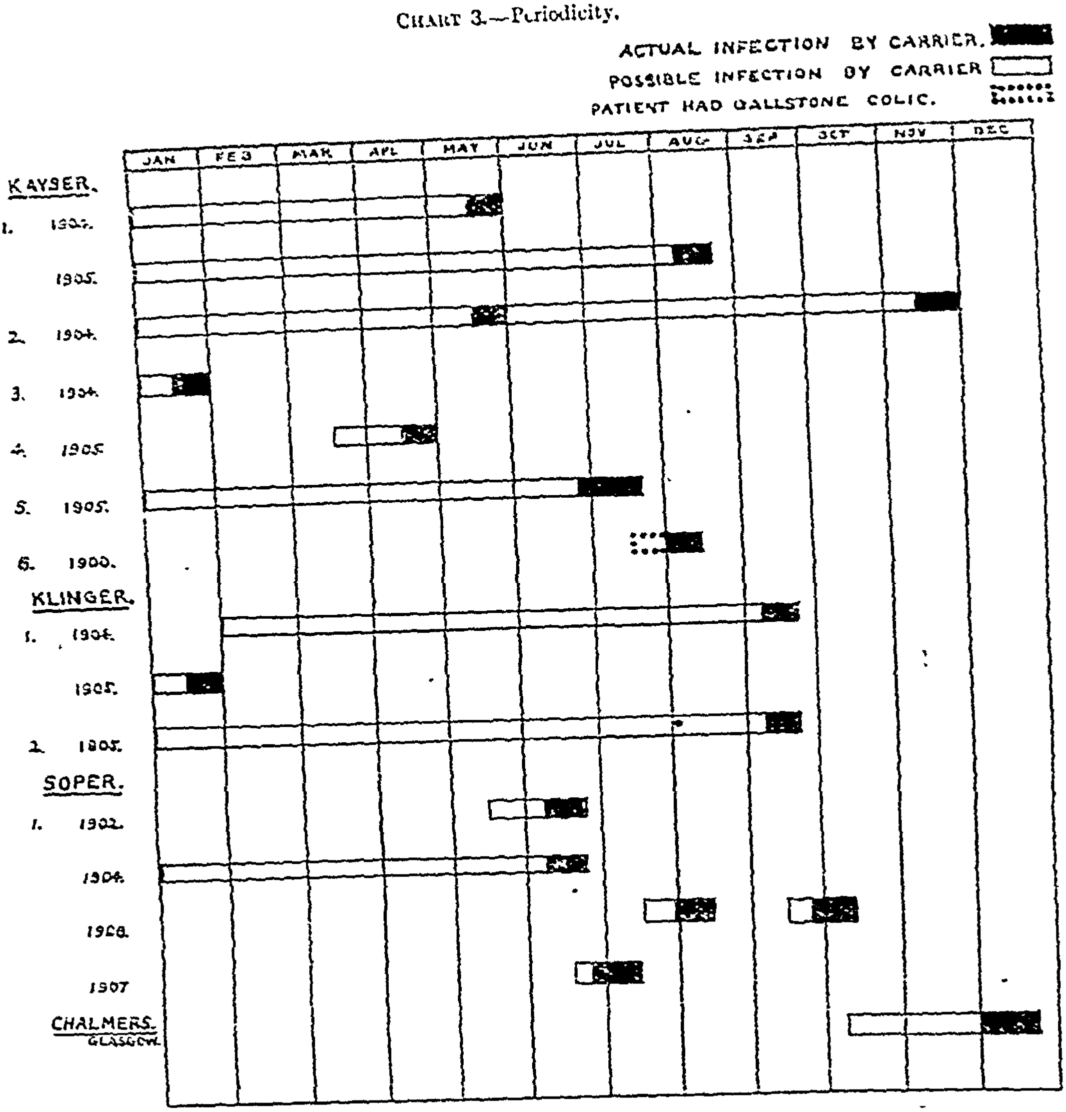

CHART 4.—Typhoid Bacilli in Fæces.

... 2.		O +	+	+	+							

The + signifies presence of typhoid bacilli and the O signifies their absence.

Without other assistance than that of the midwife he succeeded in bringing down the arms and subsequently the legs and breech; he then found that there was a second fœtus attached. He brought down the legs of the second child and had little difficulty in delivering the body and after-coming head. The monster died during delivery; the mother made an uninterrupted recovery, the perineum even having escaped laceration.—Mr. T. M. Carter read notes of a case of Rupture of Cerebral Aneurysm in a girl, aged 16 years; the early symptoms simulated hysteria. Death occurred in a few hours preceded by absolute coma. The necropsy revealed an extensive hæmorrhage at the base of the brain.—Mr. G. Munro Smith said that he had seen the patient in the earlier stages of her fatal seizure and had been misled into regarding the symptoms as hysterical.—Dr. J. R. Charles had seen her after she had become comatose and was led to diagnose cerebral hæmorrhage from the ophthalmoscopic appearances which revealed a very early stage of optic neuritis. He mentioned another case which he had seen where a similar condition was responsible for sudden death.—Professor Walker Hall described the post-mortem findings and showed direct colour photographs of microscopic sections from the dilated vessel which had burst; he was unable to say whether the vessel was an artery or vein. Apart from this lesion there were general hypoplasia of the cardio-vascular system and an abnormal fluidity of the blood which had only clotted round the ruptured vessel, but in no other part of the body.—Dr. Edgeworth said that while pathologist at the Royal Infirmary he had met with several cases of basal hæmorrhage in young adults in which, after careful examination, the source of hæmorrhage could not be found.—Dr. D. A. Alexander inquired whether there was any reason for supposing that Arthur Hallam's untimely death from a "determination of blood to the brain" was an instance of this condition.—The President remarked that the mistake of confounding such a case with hysteria would undoubtedly be made again. He asked whether there was any communication between the auricles or ventricles associated with the cardiac hypoplasia; also whether there was any ante-mortem clot which could have been dislodged and given rise to aneurysm in the brain.—The answer was in the negative to both these questions.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Professor Gilbert Barling, the President, being in the chair.—Mr. C. A. Leedham-Green showed a case illustrating the improvement which might take place in a Secondary Tuberculous Lesion of the Bladder when the primary focus had been removed. The patient was a young man who for six months prior to coming under observation had noticed that he was passing blood in his urine. On examination of the bladder with the cystoscope the blood was found to proceed from large tuberculous ulcers situated principally round the opening of the right ureter. After catheterisation of the ureters had shown that the other kidney was free from tubercle and was functioning well, the right one, which was wholly disorganised by tubercle, was removed. Almost from the day of the operation the patient's general health began to improve, as was evidenced by the rapid increase in weight. For several weeks after the nephrectomy the urine continued to show the presence of large quantities of blood, but as time went on the hæmorrhage gradually disappeared, until now, not six months from the time of operation, the urine is quite clear.—Dr. J. G. Emanuel showed a boy, aged 11 years, with a Small Pulsating Tumour in the Neck which he believed to be an aneurysm of a branch of the external carotid artery. The swelling was of the size of a hazel nut, pulsatile, and situated at the angle of the lower jaw in a line with the external carotid artery. It had been noticed for two years, and its appearance followed an attack of whooping-cough. There was no history of traumatism and there were no signs of endocarditis suggesting the possibility of an embolism having occurred. There was no evidence of congenital or acquired syphilis.—Mr. F. Victor Milward showed a child whose Spleen he had Excised at the age of 18 months. The child had made a satisfactory recovery and was in good health at the present time, seven months after the operation. A differential blood count showed a marked lymphocytosis.—Mr. L. P. Gamgee showed a specimen of a Large Enchondroma growing from the upper end of the fibula. The patient, a woman, aged 45 years, first noticed the enlargement 25 years ago, and the tumour had been growing steadily in size ever since. Until six months ago she had felt no pain in the part, but for the six months there had been a good deal of aching pain. When the patient was seen on Oct. 9th, 1908, the tumour was as large as an infant's head, bossy and irregular in outline, and of a uniform hardness. There was no adhesion of the skin and there were no signs of secondary deposits. On Oct. 16th amputation through the lower third of the femur was performed. On examination it was seen that the tumour had grown primarily from the upper end of the fibula and that it had pressed on and eroded the tibia secondarily. The upper end of the fibula, which was buried in the tumour, was greatly expanded as though the growth had in the first instance commenced in the interior of the bone; towards the surface of the growth were some patches of calcification. Microscopically the tumour had the structure of an enchondroma with a slightly fibrous matrix.—Dr. J. Miller showed a large series of Lungs of Infants cut entire and stained with Weigert's Elastic Tissue Method, illustrating various forms of pulmonary tuberculosis. Several of the sections showed cavity formation from small dilated bronchioles up to cavities occupying the whole upper lobes. In several instances the cavities were in the lower lobes, a condition found frequently in cases of abdominal tubercle.—Mr. George Heaton showed two specimens of Calculous Pyonephrosis in which a double ureter was present. The first was removed from a woman, aged 37 years, who had had symptoms of renal calculus on the left side for seven or eight years. The kidney was distended into a large multilocular pus sac. Primary lumbar nephrectomy was performed and the patient made a good recovery, and was now, 12 months after the operation, in excellent health. The upper half of the kidney was found to have a separate ureter which passed down separately from its fellow as far as it was exposed in the wound. The portion of the kidney drained by this upper ureter was comparatively healthy and contained no calculi. Preservation of any portion of the kidney was impossible at the operation, as the hæmorrhage was profuse from abnormal renal blood-vessels. The lesser half of the kidney was converted into a series of thin-walled pus sacs and contained four calculi. The second specimen was removed by lumbar nephrectomy from a woman, aged 30 years, who had a very large pyonephrosis on the left side extending from beneath the costal arch to the iliac fossa and considerably beyond the middle line laterally. The kidney was completely destroyed except for a small portion which lay between the pus sacs and the suprarenal gland and which after removal was found to have a separate ureter. This ureter was found to join the main one just beyond the pelvis of the kidney. The pyonephrosis contained one large branched calculus plugging up the mouth of the main ureter and a number of smaller calculi in the distended calyces. The patient made an excellent recovery.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 19th, Mr. T. H. Bickerton, the President, being in the chair.—Dr. Karl A. Grossmann in a note on Fibrolysin, after describing the composition of the drug, its properties, and effects on cicatricial tissues, mentioned the various medical and surgical diseases in which it was reported to have been used with good result. He then gave an account of ophthalmic cases in which he had employed it himself. Foremost amongst these was a case of severe burn of the eyelids. A thick dense scar had formed, preventing movement and causing the cornea to ulcerate. After treatment the lid opened and closed readily and its function became quite normal, so that only a small shortening of the lid remained. The patient was shown, with photographs before and after application of the drug.—Dr. Edgar Stevenson said that he had not used the drug owing to objections to its method of administration, but he had used thiosinamin for about ten years and considered it a most useful drug in the treatment of certain diseases and injuries of the eye.—Dr. R. J. M. Buchanan said that he had found fibrolysin of extreme value in a case of chronic sclerosis of the spinal cord of many years standing; under its use contractures and pain had been much relieved and ataxia lessened, and the power of walking had returned. He had found it useful in the treatment of non-tuberculous pleural adhesions and in one case of thick adhesions in the region of the gall-bladder associated with jaundice. He found that the drug had a direct local effect and if not injected deep enough under the skin would

control the action of the germs. As there is generally no need to deal with the drains, or to disinfect rooms or houses for these special cases, no upset of the domestic arrangements is necessary.

6. In the household where a patient is convalescing from typhoid fever the additional precautions of boiling all the milk or water used for drinking or in the preparation of food should be undertaken, and uncooked foods should be avoided.

THE COMMON COLD: ITS PATHOLOGY AND TREATMENT,

WITH ESPECIAL REFERENCE TO VACCINE THERAPY.[1]

By R. W. ALLEN, M.D., B.S. LOND.,

CLINICAL PATHOLOGIST, MOUNT VERNON HOSPITAL FOR CONSUMPTION; LATE PATHOLOGIST TO THE ROYAL EYE HOSPITAL AND LATE GULL RESEARCH STUDENT IN PATHOLOGY, GUY'S HOSPITAL.

I.—INTRODUCTION.

IN a recent publication on catarrhal fevers by Dr. R. Prosser White we find the following: "I venture to submit that our zeal and interest in a disease should be proportional not to its rarity but to its frequency; and to call *trifling*, a disease which incapacitates members of every class of society oftener and more commonly than any other, and has the reputation of initiating so diverse and numerous ailments, is a travesty of facts. This condition, the bane of the household and the scourge of the community is allowed to run riot, practically ignored by our leaders, our medical schools and our text-books." A feeling exactly in accord with that expressed by these very true words was the cause of my undertaking the present research into this common affection, which, again to quote Dr. Prosser White, "is a source of inconvenience, if not danger, to the strong, and is often followed by severest consequences in the old and the young, the feeble and the debilitated—which may be the active factor in overburdening an already embarrassed heart, setting up the final catarrh in the later stages of phthisis or multiplying the difficulties and distresses of the chronic invalid suffering from bronchitis and emphysema." The work conducted during two years' tenure of the Gull studentship has been completed in my private practice, with the result that I think I can fairly claim to have placed the bacteriology upon a sounder footing, indicated means whereby a differential diagnosis of the causal organism or organisms may be made in any given case from a consideration of the clinical features, and to have demonstrated the utility of vaccine therapy not only in shortening acute attacks and thereby preventing secondary complications, but also in curing chronic cases and in securing immunity, more or less complete, from further attacks, acute or chronic, in those who are especially susceptible to this very troublesome and common complaint.

II.—DEFINITION OF A COLD.

For the purposes of this research a cold may be defined as a local inflammation of any portion of the respiratory tract, from the mouth and external nasal meatus to the bifurcation of the bronchi, together with the sinuses annexed thereto; such as the frontal and ethmoidal sinuses, the maxillary antrum, and the Eustachian tube; inflammations due to the ordinary pyogenic cocci are, however, excluded. The conditions thus included are the so-called colds in the head, sore throats, and tracheal coughs. The word "fever" has been avoided, inasmuch as any rise of temperature is, more often than not, local and not general; indeed, the true body temperature, obtained either per rectum or by means of the urine, is more often than not subnormal. Colds are always acute at the onset but may go on to a chronic stage, persisting for even 20 years, punctuated at intervals by acute exacerbations. The acute cold exhibits the following stages. 1. Local anæmia of the mucous membrane. This probably precedes infection, so ought perhaps to be called a pre-catarrhal condition. This is succeeded by local hyperæmia, the natural response of the body to the preceding anæmia. 2. After infection there is a period of incubation, during which the hyperæmia increases to a greater or less extent. Few opportunities of measuring this have presented themselves, but in one case it could be fixed at only two hours; the usual period, however, seems to be about 12 hours, but varies according as to whether the infection is a fresh one from without or due to a lighting up into activity of organisms already resident in these parts. During this period there may be dryness and tickling of the palate and fauces and a few sneezes may be given, soon to be followed by a general feeling of malaise and chilliness, which marks the completion of the incubation period and the onset of the third stage—viz., the period which may be called the "catarrhal plateau." This is characterised by greatly increased mucous secretion, the attempt of the body to rid itself of the invaders. If the fauces be involved there is a definite sore-throat, if the trachea a resultant cough. The feeling of general malaise continues, often accompanied by headache, constipation, and distaste for food; there may be some pyrexia; the secretion of sweat and urine is diminished and the latter may be loaded with urates. After from 18 to 48 hours the mucous secretion diminishes and the fourth or subacute stage is entered upon. The mucous discharges become thick and contain leucocytes and lymphoid cells which cause the discharges to become yellow in colour. This lasts for a period varying from two or three days to as many weeks, when it either ceases and cure is established, or it persists for months or even years and enters upon the fifth stage, which is that of true chronicity, marked by continuous excessive secretion of thick mucus and the feeling aptly described as "stuffiness of the nose." Such a chronic condition is punctuated at intervals by periods of exacerbation or by acute attacks due to a second organism.

III.—BACTERIOLOGY.

A.—*Technique Employed.*

Before any attempt can be made at the determination of the bacterial agents in the production of pathological conditions it is obviously necessary to determine what are the normal bacterial inhabitants of the part or parts. Accordingly healthy noses and throats were examined as well as catarrhal. The technique employed was as follows.

1. *For the trachea.*—The mouth having been thoroughly gargled several times with sterile water, by means of a violent cough some mucus was expectorated and received in sterilised water; a small compact piece was washed two or three times and then inseminated upon one or more of the following—agar, blood agar, nutrose ascitic agar or so-called "nasgar," blood serum. After 24 hours' incubation at 37° C. films were prepared as well as some from the original mucus, stained with methylene blue and by Gram's method, and examined microscopically. The organisms were then isolated when necessary.

2. *For the throat.*—Swabs were taken from the hyperæmic areas, soft palate, posterior pharyngeal wall, fauces or tonsils, and treated as in the case of the tracheal mucus.

3. *For the nose.*—In order to avoid contamination with the organisms infecting the vibrissæ and vestibule the following procedures were adopted: (*a*) A piece of sterilised glass tubing about three inches long and of ample bore so as to admit the passage of a platinum loop was inserted up the nostril; along this tube a sterile loop was pushed and the protruded end rubbed over the surface of the nasal mucosa; it was then withdrawn through the glass tubing and a smear made upon agar, blood agar, blood serum, or nasgar, two or three such smears being usually made upon different media. (*b*) As an alternative method a sterilised nasal speculum was used to separate the nasal orifice and by means of a sterile swab cultures taken as high up the septum and turbinals as it was possible to get. (*c*) Experiment, however, showed that these precautions were hardly necessary in the case of nasal catarrh where organisms are always plentiful and that certain advantages were to be obtained by using the following procedure. The orifice of the nose having been well washed with warm soap and water and dried upon sterile lint, one nostril was closed and the nasal secretion forcibly expelled from the other upon sterilised cotton-wool. Ample material is thus obtained to inseminate numerous tubes and plates and to prepare films. In several cases cultures were made by two of these methods and identical results obtained.

---

[1] A thesis accepted for the M.D. degree (Branch II.), University of London.

[illegible] could have been dislodged and given rise to aneurysm in the brain.—The answer was in the negative to both these questions.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Professor Gilbert Barling, the President, being in the chair.—Mr. C. A. Leedham-Green showed a case illustrating the Improvement which might take place in a Secondary Tuberculous Lesion of the Bladder when the primary focus had been removed. The patient was a young man who for six months prior to coming under observation had noticed that he was passing blood in his urine. On examination of the bladder with the cystoscope the blood was found to proceed from large tuberculous ulcers situated principally round the opening of the right ureter. After catheterisation of the ureters had shown that the other kidney was free from tubercle and was functioning well, the right one, which was wholly disorganised by tubercle, was removed. Almost from the day of the operation the patient's general health began to improve, as was evidenced by the rapid increase in weight. For several weeks after the nephrectomy the urine continued to show the presence of large quantities of blood, but as time went on the hæmorrhage gradually disappeared, until now, not six months from the time of operation, the urine is quite clear.—Dr. J. G. Emanuel showed a boy, aged 11 years, with a Small Pulsating Tumour in the Neck which he believed to be an aneurysm of a branch of the external carotid artery. The swelling was of the size of a hazel nut, pulsatile, and situated at the angle of the lower jaw in a line with the external carotid artery. It had been noticed for two years, and its appearance followed an attack of whooping-cough. There was no history of traumatism and there were no signs of endocarditis suggesting the possibility of an embolism having occurred. There was no evidence of congenital or acquired syphilis.—Mr. F. Victor Milward showed a child whose Spleen he had Excised at the age of 18 months. The child had made a satisfactory recovery and was in good health at the present time, seven months after [illegible] blood count showed a marked [illegible] showed a specimen of a [illegible] from the upper end of the fibula. The patient, a woman, aged 45 years, first noticed the enlargement 25 years ago, and the

pus sacs and contained four calculi. [illegible] was removed by lumbar nephrectomy from a woman, aged 30 years, who had a very large pyonephrosis on the left side extending from beneath the costal arch to the iliac fossa and considerably beyond the middle line laterally. The kidney was completely destroyed except for a small portion which lay between the pus sacs and the suprarenal gland and which after removal was found to have a separate ureter. This ureter was found to join the main one just beyond the pelvis of the kidney. The pyonephrosis contained one large branched calculus plugging up the mouth of the main ureter and a number of smaller calculi in the distended calyces. The patient made an excellent recovery.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 19th, Mr. T. H. Bickerton, the President, being in the chair.—Dr. Karl A. Grossmann in a note on Fibrolysin, after describing the composition of the drug, its properties, and effects on cicatricial tissues, mentioned the various medical and surgical diseases in which it was reported to have been used with good result. He then gave an account of ophthalmic cases in which he had employed it himself. Foremost amongst these was a case of severe burn of the eyelids. A thick dense scar had formed, preventing movement and causing the cornea to ulcerate. After treatment the lid opened and closed readily and its function became quite normal, so that only a small shortening of the lid remained. The patient was shown, with photographs before and after application of the drug.—Dr. Edgar Stevenson said that he had not used the drug owing to objections to its method of administration, but he had used thiosinamin for about ten years and considered it a most useful drug in the treatment of certain diseases and injuries of the eye.—Dr. R. J. M. Buchanan said that he had found fibrolysin of extreme value in a case of chronic sclerosis of the spinal cord of many years standing; under its use contractures and pain had been much relieved and ataxia lessened, and the power of walking had returned. He had found it useful in the treatment of non-tuberculous pleural adhesions and in one case of thick adhesions in the region of the gall-bladder associated with jaundice. He found that the drug had a direct local effect and if not injected deep enough under the skin would

possess pathogenic properties, and yet these cases have neither pneumonia on the one hand nor diphtheria on the other. The important factors are, *inter alia*, first, one of pathogenicity of the organism, and, secondly, of susceptibility of the individual. These questions I have the more fully investigated in the case of the bacillus of Friedländer and the inference of its causal relationship seems amply justified.

TABLE III.—*Summary of the Bacteriology of the Cases.*

No. of case.	Nature of case.	Bacillus of Friedländer.	Bacillus influenzæ.	Bacillus septus.	Micrococcus catarrhalis.
1	Chronic 12 years.	+	—	—	—
2	Acute 2 days.	—	—	Few.	+
3	,, 1 day.	+	—	—	—
4	Acute upon chronic of 4 months.	+	—	—	—
5	Acute 1 day upon subacute of 2 weeks.	+	—	—	—
6	Acute 5 days.	+	—	Few.	—
7	,, 12 hours.	—	+	—	—
8	,, 12 ,,	—	—	+	—
9	,, 3 ,,	—	—	+	—
10	Subacute 12 days.	—	—	—	+
11	Acute 2 days.	—	—	+	+
12	,, 1 day.	—	—	—	+
13	,, 2 days.	+	—	+	—
14	,, 1 day.	—	—	+	—
15	Subacute 14 days.	—	—	+	—
16	Chronic 17 years.	+	—	—	—
17	Acute 2 days.	—	—	+	—
18	,, 3 days.	—	—	—	+
19	,, 1 day.	+	—	—	—
20	,, 1 ,,	+	—	—	—
21	,, 1 ,,	+	—	+	—
22	,, 2 hours.	+	—	—	—

25	,, 1 day.	—	—	+	+
26	,, 4 days.	—	—	+	—
27	Acute on subacute of 14 days.	—	—	—	+
28	Acute 1 day.	—	—	—	+
29	,, 2 days.	+	—	—	+
30	,, ,,	—	—	+	—
31	Acute two days upon chronic of 20 years.	+	—	—	+
32	Acute 1 day.	—	—	+	—
33	,, 3 days.	—	—	+	+
34	Chronic tracheal catarrh of 20 years.	—	—	—	+
35	Acute outburst in No. 34.	—	—	—	+
36	Acute 1 day.	—	—	—	+
37	,, 3 days.	?	—	—	—
38	,, 2 ,,	—	—	+	—
39	,, 3 ,,	—	—	—	+
40	,, 3 ,,	—	—	—	+
41	,, 1 day.	—	—	—	+
42	Chronic 10 years, with acute outbursts.	—	—	+	+

As regards pathogenicity, each strain on isolation was introduced into a rabbit, rat, and guinea-pig. In all but two cases where the animals were made extremely ill but survived for three days, when they were killed by chloroform, the animals died, usually within 24 hours. In every case the typical capsulated diplo-bacilli were recovered from the heart blood and peritoneal fluid; post mortem the animals presented areas of pneumonic lung, enlarged spleens, and, where the inoculation had been intraperitoneal, peritonitis, especially over the liver and spleen. The virulence was of a high degree.

Secondly, Case 1 was proved to have the organism continually present in large numbers in the nasal mucosa. During several exacerbations these were discharged from the nose in large numbers; within a very short time workers in the same room, whose nasal cavities had just been proved to be practically sterile and who were free from colds, developed severe attacks, during which the bacillus of Friedländer was found to be abundantly present in their nasal mucus. Further, Case 1 was finally cured both of the chronic and acute attacks by injection of a vaccine prepared from his organism and repeated cultivations have since failed to find the bacillus of Friedländer present. Again, in the instance of Case 4, a chronic one of four months' standing, the disappearance of symptoms and organism was simultaneous.

Thirdly, an emulsion of Friedländer's bacillus was spilt in the laboratory where three individuals were working; within a few hours each developed a mild catarrhal attack during which the bacillus was found in the nasal mucus.

Fourthly, reference to the opsonic charts (1 and 2) appended of Cases 1 and 16 shows that the index to Friedländer's bacillus was abnormally high during the chronic stages and that it was influenced by an exacerbation of the infection just as one would expect it to be were the acute attack due to the given organism.

Fifthly, the percentage of cases in which this organism was found was very much in excess of that found in healthy noses by von Besser, 2·5, and by Lewis and Logan Turner, 4.

The claims of the bacillus influenzæ to be regarded as a cause of nasal catarrh are too well known to require discussion, whilst those of the micrococcus catarrhalis have been well demonstrated by Dunn and Gordon[7] in the case of an epidemic in Hertfordshire which closely simulated influenza, by Pfeiffer, by Lord, and by Bezançon and de Jong in Paris.[8] By accidently sucking up some emulsion of this organism which he had prepared Gordon[9] records the onset after 24 hours of a cold which gradually extended down the trachea. From the nasal discharge he recovered the organism at the close of the attack. In Cases 2, 10, 12, 18, 23, 27, 28, 35, 36, 39, 40, and 44 this organism was obtained in practically pure culture from the nasal mucus. The patient in Case 2 was one of a household of eight who had been attacked one after the other by severe colds. Cases 27, 25, and 28 present this interesting feature—they were "contacts." Case 27 had had a subacute attack for about 14 days and developed an acute cold without sore throat. 24 hours later patient No. 25 had a severe cold beginning with a sore throat. No. 28 then came into contact with No. 25 and followed suit without a sore throat. All three patients yielded abundant growth of the micrococcus catarrhalis; from No. 25 alone was the bacillus septus in addition isolated.

As regards the capacity of the micrococcus catarrhalis to produce nasal catarrh there is then little doubt, but whether it is the direct causal agent in all catarrhal cases in which it alone is isolated is not so certain. A coccus at all events very closely allied to it is, as I have shown, an extremely common inhabitant in normal throats, perhaps even to the extent of from 70 to 80 per cent.

The claims of the bacillus septus are much more difficult to decide. It is true that Cautley[10] found it in seven out of eight cases of cold which he investigated, or in 88 per cent., Prosser White[11] in 17 out of 21, or in 81 per cent., and Benham in 25 out of 27, or in 91 per cent. My results were in 11 out of 42 cases, or 26·2 per cent., by itself, and in three others along with Friedländer's bacillus and in two with the micrococcus catarrhalis. It is true that the percentage of healthy noses which nurture this organism is between 8 and 12 per cent. and the contrast seems almost convincing. It must, however, be noted that these observers were not aware that Friedländer's bacillus could produce a cold and accordingly omitted to consider its etiological claims. In five out of his 27 cases Benham found —Gram bacilli and one of these was proved to be the bacillus of Friedländer and the others may have been; in two others the bacillus influenzæ seems to have been present, and in yet 13 other

[11] Catarrhal Fevers.

Without other assistance than that of the midwife he succeeded in bringing down the arms and subsequently the legs and breech; he then found that there was a second fœtus attached. He brought down the legs of the second child and had little difficulty in delivering the body and after-coming head. The monster died during delivery; the mother made an uninterrupted recovery, the perineum even having escaped laceration.—Mr. T. M. Carter read notes of a case of Rupture of Cerebral Aneurysm in a girl, aged 16 years; the early symptoms simulated hysteria. Death occurred in a few hours preceded by absolute coma. The necropsy revealed an extensive hæmorrhage at the base of the brain.—Mr. G. Munro Smith said that he had seen the patient in the earlier stages of her fatal seizure and had been misled into regarding the symptoms as hysterical.—Dr. J. R. Charles had seen her after she had become comatose and was led to diagnose cerebral hæmorrhage from the ophthalmoscopic appearances which revealed a very early stage of optic neuritis. He mentioned another case which he had seen where a similar condition was responsible for sudden death.—Professor Walker Hall described the post-mortem findings and showed direct colour photographs of microscopic sections from the dilated vessel which had burst; he was unable to say whether the vessel was an artery or vein. Apart from this lesion there were general hypoplasia of the cardio-vascular system and an abnormal fluidity of the blood which had only clotted round the ruptured vessel, but in no other part of the body.—Dr. Edgeworth said that while pathologist at the Royal Infirmary he had met with several cases of basal hæmorrhage in young adults in which, after careful examination, the source of hæmorrhage could not be found.—Dr. D. A. Alexander inquired whether there was any reason for supposing that Arthur Hallam's untimely death from a "determination of blood to the brain" was an instance of this condition.—The President remarked that the mistake of confounding such a case with hysteria would undoubtedly be made again. He asked whether there was any communication between the auricles or ventricles associated with the cardiac hypoplasia; also whether there was any ante-mortem clot which could have been dislodged and given rise to aneurysm in the brain.—The answer was in the negative to both these questions.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Professor Gilbert Barling, the President, being in the chair.—Mr. C. A. Leedham-Green showed a case illustrating the improvement which might take place in a Secondary Tuberculous Lesion of the Bladder when the primary focus had been removed. The patient was a young man who for six months prior to coming under observation had noticed that he was passing blood in his urine. On examination of the bladder with the cystoscope the blood was found to proceed from large tuberculous ulcers situated principally round the opening of the right ureter. After catheterisation of the ureters had shown that the other kidney was free from tubercle and was functioning well, the right one, which was wholly disorganised by tubercle, was removed. Almost from the day of the operation the patient's general health began to improve, as was evidenced by the rapid increase in weight. For several weeks after the nephrectomy the urine continued to show the presence of large quantities of blood, but as time went on the hæmorrhage gradually disappeared, until now, not six months from the time of operation, the urine is quite clear.—Dr. J. G. Emanuel showed a boy, aged 11 years, with a Small Pulsating Tumour in the Neck which he believed to be an aneurysm of a branch of the external carotid artery. The swelling was of the size of a hazel nut, pulsatile, and situated at the angle of the lower jaw in a line with the external carotid artery. It had been noticed for two years, and its appearance followed an attack of whooping-cough. There was no history of traumatism and there were no signs of endocarditis suggesting the possibility of an embolism having occurred. There was no evidence of congenital or acquired syphilis.—Mr. F. Victor Milward showed a child whose Spleen he had Excised at the age of 18 months. The child had made a satisfactory recovery and was in good health at the present time, seven months after the operation. A differential blood count showed a marked lymphocytosis.—Mr. L. P. Gamgee showed a specimen of a Large Enchondroma growing from the upper end of the fibula. The patient, a woman, aged 45 years, first noticed the enlargement 25 years ago, and the tumour had been growing steadily in size ever since. Until six months ago she had felt no pain in the part, but for the six months there had been a good deal of aching pain. When the patient was seen on Oct. 9th, 1908, the tumour was as large as an infant's head, bossy and irregular in outline, and of a uniform hardness. There was no adhesion of the skin and there were no signs of secondary deposits. On Oct. 16th amputation through the lower third of the femur was performed. On examination it was seen that the tumour had grown primarily from the upper end of the fibula and that it had pressed on and eroded the tibia secondarily. The upper end of the fibula, which was buried in the tumour, was greatly expanded as though the growth had in the first instance commenced in the interior of the bone; towards the surface of the growth were some patches of calcification. Microscopically the tumour had the structure of an enchondroma with a slightly fibrous matrix.—Dr. J. Miller showed a large series of Lungs of Infants cut entire and stained with Weigert's Elastic Tissue Method, illustrating various forms of pulmonary tuberculosis. Several of the sections showed cavity formation from small dilated bronchioles up to cavities occupying the whole upper lobes. In several instances the cavities were in the lower lobes, a condition found frequently in cases of abdominal tubercle.—Mr. George Heaton showed two specimens of Calculous Pyonephrosis in which a double ureter was present. The first was removed from a woman, aged 37 years, who had had symptoms of renal calculus on the left side for seven or eight years. The kidney was distended into a large multilocular pus sac. Primary lumbar nephrectomy was performed and the patient made a good recovery, and was now, 12 months after the operation, in excellent health. The upper half of the kidney was found to have a separate ureter which passed down separately from its fellow as far as it was exposed in the wound. The portion of the kidney drained by this upper ureter was comparatively healthy and contained no calculi. Preservation of any portion of the kidney was impossible at the operation, as the hæmorrhage was profuse from abnormal renal blood-vessels. The lesser half of the kidney was converted into a series of thin-walled pus sacs and contained four calculi. The second specimen was removed by lumbar nephrectomy from a woman, aged 30 years, who had a very large pyonephrosis on the left side extending from beneath the costal arch to the iliac fossa and considerably beyond the middle line laterally. The kidney was completely destroyed except for a small portion which lay between the pus sacs and the suprarenal gland and which after removal was found to have a separate ureter. This ureter was found to join the main one just beyond the pelvis of the kidney. The pyonephrosis contained one large branched calculus plugging up the mouth of the main ureter and a number of smaller calculi in the distended calyces. The patient made an excellent recovery.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 19th, Mr. T. H. Bickerton, the President, being in the chair.—Dr. Karl A. Grossmann in a note on Fibrolysin, after describing the composition of the drug, its properties, and effects on cicatricial tissues, mentioned the various medical and surgical diseases in which it was reported to have been used with good result. He then gave an account of ophthalmic cases in which he had employed it himself. Foremost amongst these was a case of severe burn of the eyelids. A thick dense scar had formed, preventing movement and causing the cornea to ulcerate. After treatment the lid opened and closed readily and its function became quite normal, so that only a small shortening of the lid remained. The patient was shown, with photographs before and after application of the drug.—Dr. Edgar Stevenson said that he had not used the drug owing to objections to its method of administration, but he had used thiosinamin for about ten years and considered it a most useful drug in the treatment of certain diseases and injuries of the eye.—Dr. R. J. M. Buchanan said that he had found fibrolysin of extreme value in a case of chronic sclerosis of the spinal cord of many years standing; under its use contractures and pain had been much relieved and ataxia lessened, and the power of walking had returned. He had found it useful in the treatment of non-tuberculous pleural adhesions and in one case of thick adhesions in the region of the gall-bladder associated with jaundice. He found that the drug had a direct local effect and if not injected deep enough under the skin would

bacillus septus is the production of the sore throat. The fact that in my 220 cases of sore throats the percentage in which this organism was found was only 27 against a percentage of 45 for normal throats would seem to negative this view; but I think that chance, the time of year, or some other factor decreed that my figures for healthy throats should be much too high, for other observers have found the percentage to be between 8 and 12 per cent. To sum up, I believe that the bacillus septus is the true etiological factor in the production of a certain percentage of colds, but that through neglect to use appropriate media and to observe the occurrence of the other possible organisms certain observers have obtained much too high a figure and have been thereby led to the belief that it is *the* cause of the common cold.

As regards the micrococcus paratetragenus, which was not present in any of my cases, ample evidence of pathogenicity is forthcoming. Thus, Bezançon[12] found it in the blood of a patient dying from endocarditis, in a case of fatal pulmonary gangrene, and in the cerebro-spinal fluid of a patient in whom paraplegia followed upon pulmonary infection due to this organism. Not only did he find it in a state of practical purity in the sputum of cases of bronchitis and broncho-pneumonia but also in all those of angina with pultaceous exudate during the winter of 1904-05. Benham[13] records similar results at Brighton during 1907-08.

Three other important considerations there are which strongly substantiate the view that these organisms stand in a directly causal relationship to the common cold. First, that during any given epidemic a diagnosis of the organism present can almost infallibly be made, as is shown later, from consideration of the symptoms, each organism producing its own type of cold; secondly, that during any given epidemic of colds the same organism is recoverable from practically every case in pure culture; and thirdly, that subsequent immunity can be secured by injections at suitable intervals of vaccines of these organisms.

If the results given in Table IV. be compared with those obtained by Benham[14] it will be seen that the symptoms caused by the micrococcus catarrhalis and the micrococcus paratetragenus closely resemble each other.

IV.—DIFFERENTIAL DIAGNOSIS OF THE SEVERAL VARIETIES OF COLD.

Each organism produces a more or less distinct type of cold. If only one organism be present the differential diagnosis is, as a rule, easy, but when two occur together, as in six of my cases, the difficulty is greater. Division of colds into acute, subacute, and chronic facilitates the consideration—by subacute I mean lasting from two to three months, with an occasional slight exacerbation; by chronic those that persist over six months, even to 20 years. Examination of Table IV. will show that the following scheme may be drawn up:—

—	Bacillus of Friedländer.	Bacillus influenzæ.	Bacillus septus.	Micrococcus catarrhalis.
Acute	+	+	+	+
Subacute ...	+	No.	Rarely.	+
Chronic... ...	+	—	—	+

Thus we see that the only three cases of truly chronic nasal catarrh which were fully investigated were all due to the bacillus of Friedländer.

While the micrococcus catarrhalis is probably largely responsible for chronic tracheitis—though secondary infection by staphylococci, streptococci, and more or less avirulent pneumococci also probably plays an important part—it would not appear to cause a chronic nasal catarrh, unless perhaps in cases where the infection extends to the accessory sinuses, and especially the Eustachian tube as in Case 42.

Subacute colds appear to be due to either the bacillus of Friedlander or to the micrococcus catarrhalis or micrococcus paratetragenus. The two latter fall into this category from their great tendency to invade the trachea and bronchi. Neither the bacillus of Friedländer nor the bacillus septus, so far as I am aware, induces catarrh of the trachea; the former probably does in those cases of pneumonia for which it is responsible, but after all these are not common. I have never recovered the bacillus septus from tracheal mucus. The persistent hacking tracheal or "winter" cough is thus probably due either to the micrococcus catarrhalis or micrococcus paratetragenus. Not only does the bacillus of Friedländer fail to affect the trachea, but it also does not cause a painful throat, differing in this both from the bacillus septus and the micrococcus catarrhalis. It confines its attention to the nose and accessory sinuses and the post-nasal space.

The differential diagnosis of the acute forms of cold is not very difficult. The mode of onset and the condition of the throat are very helpful. If the first symptoms affect the fauces and pharynx either the micrococcus catarrhalis or the bacillus septus is certainly present; if the larynx and trachea become speedily involved the former of these or micrococcus paratetragenus is indicated; to hear a patient coughing is quite sufficient to enable a diagnosis of micrococcus catarrhalis or micrococcus paratetragenus to be made. The severity of the constitutional symptoms also varies: those of the bacillus septus are but slight, those of the micrococcus paratetragenus are moderate unless the epidemic assume a broncho-pneumonic type, while the lassitude and mental depression in the cases of the three others, and especially of influenza, may be extreme. The temperature is high as a rule (from 100° to 104° F.) only in the case of influenza and is often accompanied by a relatively slow pulse. Other systems, such as the circulatory, nervous, or digestive, also frequently become involved. Nasal catarrh, as a rule, is slight and much yellowish-green lumpy mucus may be expectorated swarming with the bacilli. In the cases due to Friedländer's bacillus the temperature rarely rises above 99·5°, and the pulse is not slow, nor do other systems become involved. The flow of nasal mucus is always extreme; in one case it was found to be between 15 and 20 cubic centimetres per hour.

Value of differential diagnosis in prognosis.—The bacillus of Friedländer being probably the only cause of a chronic nasal catarrh and the risk of involvement of the Eustachian tube, middle ear, and accessory sinuses being considerable, the prognosis in the case of this organism should be very guarded and much greater care should be taken by the patient. As will be mentioned later, the risks of chronicity can be considerably reduced by the administration of an autogenous vaccine.

In the case of the bacillus septus even sub-chronicity is rare and complications of any sort are very little to be dreaded; this is the type of cold which gets well of itself with very little attention and a good prognosis can therefore be given.

The case of the micrococcus catarrhalis stands upon a different footing and the prognosis must be much more guarded. Extension to the Eustachian tube and middle ear is not altogether infrequent, while downward extension to the trachea and bronchi is habitual.[15] A persistence of the cough is therefore to be anticipated and possible bronchial complications are to be feared. I doubt if these latter ever occur with the bacillus septus and probably but rarely with the bacillus of Friedländer. The nervous, digestive, and circulatory systems are also liable to be affected.

These remarks about the micrococcus catarrhalis probably hold with additional force in the case of the bacillus influenzæ, but of this I cannot speak from experience, having only encountered one mild case during the past four years.

In the case of the micrococcus paratetragenus the chief danger would appear to be bronchitis and broncho-pneumonia, as in Bezançon and de Jong's cases.

V.—CAUSATION OF COLDS.

It may be granted that the essential factor is the occurrence of infection; infection alone, however, is insufficient unless the dose of organisms be sufficiently large and their virulence sufficiently great. As we have seen, from 8 to 12 per cent. of healthy noses contain diphtheroids and from 2·5 to 4·0 per cent. Friedländer's bacillus; similarly a considerable percentage of throats harbour pneumococci and from a case of Pyonephrosis associated with Insanity. After the nephrectomy there was a rapid disappearance of the mental symptoms. 2. Tuberculous epididymitis from a patient aged 70 years. Many years before he had been tapped for ascites.—Mr. W. Thompson showed a Loose Body from the Peritoneum found in the Sac of an Umbilical Hernia. The body contained fæcal concretion.—Mr. Grünbaum showed a section of a Tumour from a case of Neoplastic Diathesis. It was remarkable in showing both carcinoma and sarcoma in close proximity to each other.—Dr. W. H. Maxwell Telling showed a specimen of a Small Traction Diverticulum of the Œsophagus which by perforation had caused gangrene of the lung, suppurative mediastinitis, and pericarditis.—Mr. J. F. Dobson showed a specimen of Endothelioma of the Submaxillary Gland.

[14] Loc. cit.

[15] Barker described before the Surgical Section of the Royal Society of Medicine on March 10th last a case of meningitis secondary to otitis media, which in turn must have been secondary to a nasal catarrh. The micrococcus catarrhalis was obtained in pure culture from the middle ear and meninges.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Nov. 11th, Dr. W. Milligan, the President, being in the chair.—Professor J. Lorrain Smith discussed the equivocal results which have been obtained in the attempt to study the pathogenic action of bacillus coli by means of (*a*) agglutination, (*b*) opsonic index, and (*c*) bactericidal action of the serum. He pointed out that as yet no clue of this kind had been discovered by means of which the effects in the body of bacillus coli infections might be followed. He then dealt with the loss of bactericidal power in the glandular secretions in cases of bacillus coli infection, (*a*) in the bile, where the bacillus flourishes, (*b*) in the pancreatic juice where the bacilli are as a rule absent even in cases where the liver is invaded, and (*c*) in the intestine, where the normal regulation of bacterial growth is disturbed. He also dealt with the occasional failure of alkaline treatment in pyelitis and suggested that this was probably due to the establishment of necrotic foci in the tissues where the bacilli could grow in spite of the inhibitory influence of the alkali.—Dr. C. Christopher Heywood read a paper on Calmette's Tuberculin Reaction and considered the claims of Calmette that the reaction is easy of application, harmless, and trustworthy. He thought that the test was practically harmless if the strength of the tuberculin used was never greater than 0·1 per cent. Excessive reaction was almost always due to the use of too strong a solution or to repeating the test on the same eye at too short an interval. It was not infrequent, even with a weak solution, to get a phlyctenular conjunctivitis. In considering the trustworthiness of the test he analysed the results of 127 cases. Of these 37 were definitely tuberculous and all except four gave the reaction. The four negative cases died in a short time. There were 20 "doubtful" cases and of these 13 gave a positive and seven a negative reaction; practically all the seven negative cases proved to be not tuberculous. Of the remaining cases (70) thought not to be tuberculous, ten gave a positive and 60 a negative reaction. The ten positive cases included seven cases of chorea and Dr. Heywood's experience was that 50 per cent. of cases of chorea gave a positive reaction. He summed up by saying that he considered the negative reaction to be more trustworthy than the positive.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Dr. P. Boobbyer, the President, being in the chair.—A motion, proposed by Dr. A. C. Reid and seconded by Dr. W. Hunter, earnestly requesting the corporation of Nottingham to make provision for the erection and maintenance of a municipal crematorium in the future, was agreed to by a large majority. —Mr. W. Morley Willis, in a paper entitled "The Surgeon's Night-bell," alluded to some of the emergencies which might need immediate operation at any hour. In the case of perforated gastric ulcers no one factor had such a favourable influence on operation as early diagnosis and immediate resort to it. Of cases operated on within 12 hours of the accident occurring 80 per cent. recovered, whereas if operation were postponed to 36 hours or longer the prospect of cure became very remote. In certain cases, however, the area of peritoneum contaminated was limited by adhesions, and such cases, both clinically and in the matter of prognosis, were subacute rather than acute. For anatomical reasons Mr. Willis urged the erect rather than a recumbent posture for the patient before operation, for it was better that contaminating material escaped from the stomach should gravitate towards the pelvis rather than remain in the neighbourhood of the diaphragm, and it was found as a matter of experience that perforation usually occurred near the lesser curvature. After illustrating his paper by an account of several cases which had been under his own care, Mr. Willis passed on to the consideration of cases of ruptured ectopic gestation, in which, as a rule, speedy operation gave the patient her best chance of recovery. A specimen of a ruptured tubal sac of the size of a large walnut removed from a patient with a successful result was shown. In this case transfusion of saline solution had to be resorted to as the patient was extremely collapsed at the time of operation, from four to five pints of clotted blood and fluid being found free in the abdomen.—The paper was discussed by the President, Dr. J. Watson, Dr. J. A. Waring, Dr. Hunter, Dr. F. H. Jacob, Dr. J. S. Bolton, Dr. R. Heelis, Dr. A. J. Sharp, and Dr. J. H. Thompson, and Mr. Willis replied.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Nov. 17th, Dr. C. C. Heywood being in the chair.—Mr. E. Stanmore Bishop read a short paper on Some Points in Gastric Surgery, illustrated by lantern slides. After depicting on the screen radiographs of a normal and of a dilated stomach, Mr. Bishop discussed the effect of posture upon the outline of that organ. He then proceeded to set forth the views of different authorities upon the effects of gastro-enterostomy: (1) it might be regarded as a means of drainage and giving rest to the stomach; (2) it acted as a safety valve in cases of obstruction; and (3) it might act in both ways at different times. In support of the last view the speaker drew an analogy between the stomach after the operation of gastro-enterostomy and the male urethra when a perineal opening had been surgically established in cases of strictures. Mr. Bishop then showed on the screen the results of observations upon stomachs made by himself and Dr. Barclay by means of the x rays, after the performance of gastro-enterostomy for gastric ulcer, &c., noting especially the route by which farinaceous food left the stomach. Finally, Mr. Bishop exhibited and discussed several forms of stomach clamps, with special reference to the advantages to be derived from the use of a pattern introduced by himself.—Dr. E. Vipont Brown gave a brief description of two cases of Malignant Disease treated with Trypsin, and set forth that although no cure could be claimed the condition of the patients had been so ameliorated that this method of treatment should receive a more extensive trial.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 19th, Dr. George Williamson, the retiring President, being in the chair.—The annual report of the council was submitted and adopted and the following office-bearers were elected for the session 1908–09:—President: Dr. David Rennet. Vice-President: Dr. John Marnoch. Secretary: Dr. G. M. Duncan. Assistant Secretary: Dr. Henry Peterkin. Recording Secretary: Dr. Thomas Fraser. Treasurer: Dr. A. H. Lister. Librarian: Dr. P. Howie. Members of council: Dr. J. F. Christie, Dr. G. M. Edmond, Dr. H. M. W. Gray, Dr. J. Gordon, Dr. A. W. Mackintosh, Dr. H. Peterkin, Dr. G. Rose, and Dr. George Williamson.

Squire's Companion to the British Pharmacopœia. By PETER WYATT SQUIRE. Eighteenth edition. *London*: J. & A. Churchill. 1908. Pp. 1459. Price 14*s.* net.

To give its full and perfectly justifiable title this work is a companion to the latest edition of the British Pharmacopœia, comparing the strength of the various preparations in that official work with those of the United States and other pharmacopœias, to which are added preparations which are not official, together with practical hints on prescribing. This, the eighteenth edition, has been demanded in view of the extraordinary advances which have been made in chemistry, pharmacology, and pharmacy during the last decade. Splendidly as the "Companion" has served in the past so is it calculated to serve equally in the future, for no pains have been spared to of importance in the family history. Her father, three sisters, and one brother were alive and well.

History of eruption.—In the middle of March—i.e., six weeks before the first consultation—the patient had observed tiny elevations, grey and rough to the touch, on the outer aspects of both thighs, but especially marked on the right thigh. These had increased in number and a week or two later a redness had spread between the lesions on the right thigh. This redness was accompanied by itching. About the beginning of April groups of similar grey rough elevations had begun to appear on the chest and abdomen. Towards the end of April she had observed a few red spots on the right forearm of a quite different nature to the other parts of the eruption. This had so alarmed her that she decided to seek advice.

Appearance of eruption when first seen at the end of April.—An eruption was present on the outer aspects of both thighs, very marked on the right side; a few patches were present on the chest, abdomen, and slightly on the back of the neck and on the right arm near the elbow. The eruption presented three totally distinct clinical appearances:—

1. The eruption had commenced on the outer side of the right thigh, and in that situation there was an irregular dark-red patch over 4 inches long and between 2 and 3 inches broad. It was thickened and infiltrated; the red surface was not burnished. The patch was thickly covered with grey spines which protruded ⅛th inch from the widened orifices of the hair follicles. They could be picked out, being hard, grey, and horny, and left a gaping depression. In the neighbourhood of the patch were discrete smaller horny spines without intervening redness, and these were said to be of very recent origin. A section was taken from the middle of this patch (Section 1).

2. On the right arm near the elbow were four distinct small papules of lichen planus. They had the typical waxy, flattened, polygonal papules of that disease. A section was taken from one of them.

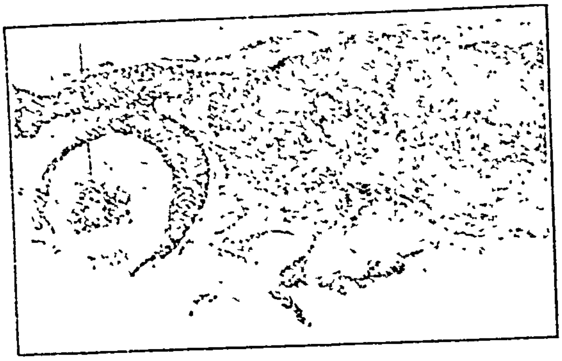
3. On the chest, neck, and abdomen were several groups of grey horny spines without any surrounding papular elevation or redness. Each group was of about the size of a threepenny-bit. There were no intervening redness and no itching. The spines could be picked out with the forceps with but little difficulty, and left a small depression behind. Some of the smaller ones resembled an exaggerated keratosis pilaris. No section was taken at this time (April).

Subsequent progress.—Simple emollient treatment consisting of lard and linseed oil with 20 grains of calamine to the unce was applied externally. A digestive mixture was aken by the mouth. In the middle of June, after six weeks f such treatment, the condition was as follows: (1) The pines on the thigh had become diminished in size but the nfiltrated redness had improved but little; (2) on the right and left arms many new papules of lichen planus had appeared; and (3) on the chest and abdomen the spines were shorter, but around most of them a degree of congestion had appeared, and in a few groups this redness had spread over the entire patch. Coincident with the appearance of this redness there was a marked degree of itching. New groups of grey horny spines without redness had also appeared on the trunk, the individual lesions resembling to the eye an exaggerated keratosis pilaris. A section was taken from a group on the chest which seemed to be progressing with congestion (Section 2). As the disease appeared to be progressing the treatment was altered. Salicylic ointment was given externally, and internally a mixture containing phosphoric acid and strychnine. I had noticed in certain cases of lichen planus that phosphoric acid had done good when the usually recommended remedies had failed. The result was equally remarkable in this case. 1. The infiltration of the thigh rapidly diminished and after three weeks the horny spines ceased to protrude. 2. No new lichen planus papules appeared on the arms; those already present gradually faded away. 3. No fresh spinous lesions appeared on the chest or other parts of the trunk, and the redness between the spines began to fade within a week.

By Sept. 1st (1) the infiltration had quite disappeared from the thick patch on the thigh, and it only presented a pigmented appearance. No spines could be found on it. Scattered over the legs were a few discrete papules like keratosis pilaris; the patient admitted having paid no attention to these and had not applied any ointment to them. 2. The lichen planus papules on the arms had entirely disappeared. 3. On the trunk all the groups of papules had so greatly improved that they had the appearance of groups of comedones; the blackened summits of many of them increased this resemblance. On picking up the skin between the finger and thumb and squeezing it firmly the contents of these follicles were easily extruded. In June these horny cores had been too adherent to the follicular walls to be squeezed out, and when picked out with forceps they had appeared dirty grey, hard, and opaque. In September the cores were bright, greyish-white in colour; when rubbed between the fingers they were resistant and did not flatten into a sticky mass as does sebaceous material obtained from comedones. Under the microscope these cores were found to consist of lamellæ of horny material with a central downy hair.

Histological appearances.—*Section 1* (Fig. 1) was excised from the infiltrated patch on the thigh at the end of April at the first consultation and showed the typical histological appearances of a patch of lichen planus—namely, the horny layer thickened, the stratum granulosum unduly marked, the hyaline alteration of the rete, and the flattened papillary processes, due to the presence of the continuous band of small-celled infiltration in the papillary body. These changes involved the hair follicles also. They were widely distended with increased horny layer, a mononucleated infiltration was present immediately beneath the epithelium, and a slight degree of œdema was evident near some of the follicles between the epithelium and the cutis. The swollen hyaline alteration of the follicular epithelium was as marked as in the neighbouring epithelium of the lichen patch between the follicles.

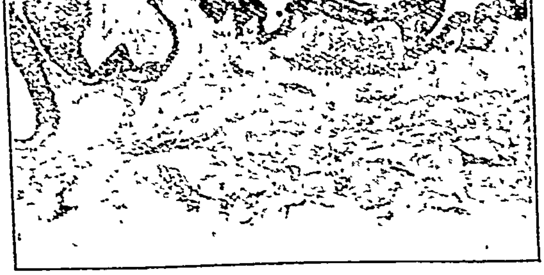
FIG. 1.



Section taken from patch on the thigh.

Section 2 was taken in June from the chest. The group of spiny processes from which the section was taken had been under observation for two months and was showing signs of progression—that is to say, a rosy tint was beginning to spread between the spines, and some of the spines were the central point of a small congested papule. A large numbe

FIG. 2.



Section taken from patch on the chest.

from a case of Pyonephrosis associated with Insanity. After the nephrectomy there was a rapid disappearance of the mental symptoms. 2. Tuberculous epididymitis from a patient aged 70 years. Many years before he had been tapped for ascites.—Mr. W. Thompson showed a Loose Body from the Peritoneum found in the Sac of an Umbilical Hernia. The body contained fæcal concretion.—Mr. Grünbaum showed a section of a Tumour from a case of Neoplastic Diathesis. It was remarkable in showing both carcinoma and sarcoma in close proximity to each other.—Dr. W. H. Maxwell Telling showed a specimen of a Small Traction Diverticulum of the Œsophagus which by perforation had caused gangrene of the lung, suppurative mediastinitis, and pericarditis.—Mr. J. F. Dobson showed a specimen of Endothelioma of the Submaxillary Gland.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Nov. 11th, Dr. W. Milligan, the President, being in the chair.—Professor J. Lorrain Smith discussed the equivocal results which have been obtained in the attempt to study the pathogenic action of bacillus coli by means of (*a*) agglutination, (*b*) opsonic index, and (*c*) bactericidal action of the serum. He pointed out that as yet no clue of this kind had been discovered by means of which the effects in the body of bacillus coli infections might be followed. He then dealt with the loss of bactericidal power in the glandular secretions in cases of bacillus coli infection, (*a*) in the bile, where the bacillus flourishes, (*b*) in the pancreatic juice where the bacilli are as a rule absent even in cases where the liver is invaded, and (*c*) in the intestine, where the normal regulation of bacterial growth is disturbed. He also dealt with the occasional failure of alkaline treatment in pyelitis and suggested that this was probably due to the establishment of necrotic foci in the tissues where the bacilli could grow in spite of the inhibitory influence of the alkali.—Dr. C. Christopher Heywood read a paper on Calmette's Tuberculin Reaction and considered the claims of Calmette that the reaction is easy of application, harmless, and trustworthy. He thought that the test was practically harmless if the strength of the tuberculin used was never greater than 0·1 per cent. Excessive reaction was almost always due to the use of too strong a solution or to repeating the test on the same eye at too short an interval. It was not infrequent, even with a weak solution, to get a phlyctenular conjunctivitis. In considering the trustworthiness of the test he analysed the results of 127 cases. Of these 37 were definitely tuberculous and all except four gave the reaction. The four negative cases died in a short time. There were 20 "doubtful" cases and of these 13 gave a positive and seven a negative reaction; practically all the seven negative cases proved to be not tuberculous. Of the remaining cases (70) thought not to be tuberculous, ten gave a positive and 60 a negative reaction. The ten positive cases included seven cases of chorea and Dr. Heywood's experience was that 50 per cent. of cases of chorea gave a positive reaction. He summed up by saying that he considered the negative reaction to be more trustworthy than the positive.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Dr. P. Boobbyer, the President, being in the chair.—A motion, proposed by Dr. A. C. Reid and seconded by Dr. W. Hunter, earnestly requesting the corporation of Nottingham to make provision for the erection and maintenance of a municipal crematorium in the future, was agreed to by a large majority.—Mr. W. Morley Willis, in a paper entitled "The Surgeon's Night-bell," alluded to some of the emergencies which might need immediate operation at any hour. In the case of perforated gastric ulcers no one factor had such a favourable influence on operation as early diagnosis and immediate resort to it. Of cases operated on within 12 hours of the accident occurring 80 per cent. recovered, whereas if operation were postponed to 36 hours or longer the prospect of cure became very remote. In certain cases, however, the area of peritoneum contaminated was limited by adhesions, and such cases, both clinically and in the matter of prognosis, were subacute rather than acute. For anatomical reasons Mr. Willis urged the erect rather than a recumbent posture for the patient before operation, for it was better that contaminating material escaped from the stomach should gravitate towards the pelvis rather than remain in the neighbourhood of the diaphragm, and it was found as a matter of experience that perforation usually occurred near the lesser curvature. After illustrating his paper by an account of several cases which had been under his own care, Mr. Willis passed on to the consideration of cases of ruptured ectopic gestation, in which, as a rule, speedy operation gave the patient her best chance of recovery. A specimen of a ruptured tubal sac of the size of a large walnut removed from a patient with a successful result was shown. In this case transfusion of saline solution had to be resorted to as the patient was extremely collapsed at the time of operation, from four to five pints of clotted blood and fluid being found free in the abdomen.—The paper was discussed by the President, Dr. J. Watson, Dr. J. A. Waring, Dr. Hunter, Dr. F. H. Jacob, Dr. J. S. Bolton, Dr. R. Heelis, Dr. A. J. Sharp, and Dr. J. H. Thompson, and Mr. Willis replied.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Nov. 17th, Dr. C. C. Heywood being in the chair.—Mr. E. Stanmore Bishop read a short paper on Some Points in Gastric Surgery, illustrated by lantern slides. After depicting on the screen radiographs of a normal and of a dilated stomach, Mr. Bishop discussed the effect of posture upon the outline of that organ. He then proceeded to set forth the views of different authorities upon the effects of gastro-enterostomy: (1) it might be regarded as a means of drainage and giving rest to the stomach; (2) it acted as a safety valve in cases of obstruction; and (3) it might act in both ways at different times. In support of the last view the speaker drew an analogy between the stomach after the operation of gastro-enterostomy and the male urethra when a perineal opening had been surgically established in cases of strictures. Mr. Bishop then showed on the screen the results of observations upon stomachs made by himself and Dr. Barclay by means of the x rays, after the performance of gastro-enterostomy for gastric ulcer, &c., noting especially the route by which farinaceous food left the stomach. Finally, Mr. Bishop exhibited and discussed several forms of stomach clamps, with special reference to the advantages to be derived from the use of a pattern introduced by himself.—Dr. E. Vipont Brown gave a brief description of two cases of Malignant Disease treated with Trypsin, and set forth that although no cure could be claimed the condition of the patients had been so ameliorated that this method of treatment should receive a more extensive trial.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 19th, Dr. George Williamson, the retiring President, being in the chair.—The annual report of the council was submitted and adopted and the following office-bearers were elected for the session 1908-09:—President: Dr. David Rennet. Vice-President: Dr. John Marnoch. Secretary: Dr. G. M. Duncan. Assistant Secretary: Dr. Henry Peterkin. Recording Secretary: Dr. Thomas Fraser. Treasurer: Dr. A. H. Lister. Librarian: Dr. P. Howie. Members of council: Dr. J. F. Christie, Dr. G. M. Edmond, Dr. H. M. W. Gray, Dr. J. Gordon, Dr. A. W. Mackintosh, Dr. H. Peterkin, Dr. G. Rose, and Dr. George Williamson.

Squire's Companion to the British Pharmacopœia. By PETER WYATT SQUIRE. Eighteenth edition. London: J. & A. Churchill. 1908. Pp. 1459. Price 14s. net.

To give its full and perfectly justifiable title this work is a companion to the latest edition of the British Pharmacopœia, comparing the strength of the various preparations in that official work with those of the United States and other pharmacopœias, to which are added preparations which are not official, together with practical hints on prescribing. This, the eighteenth edition, has been demanded in view of the extraordinary advances which have been made in chemistry, pharmacology, and pharmacy during the last decade. Splendidly as the "Companion" has served in the past so is it calculated to serve equally in the future, for no pains have been spared to

THE

STERILISATION OF POTABLE WATERS BY MEANS OF CALCIUM HYPOCHLORITE.

BY JOHN C. THRESH, M.D. VICT., D.SC. LOND., F.I.C.,
LECTURER ON PUBLIC HEALTH, LONDON HOSPITAL MEDICAL COLLEGE; MEDICAL OFFICER OF HEALTH, ESSEX COUNTY COUNCIL.

AT the present time I have under observation several important public water supplies which are invariably satisfactory from a chemical point of view but which from time to time contain bacillus coli in small numbers, indicating some slight pollution with water of an objectionable, if not dangerous, character. In some instances experiments made with fluorescein have enabled the source of the undesirable water to be discovered but in others efforts made to discover the source of pollution have failed. In certain of these cases an enormous expense would have to be incurred to obtain a safer source of supply, in others the available sources are just as likely to be contaminated as those at present in use. The problem of finding a means of purifying such waters has therefore engaged my attention for some time and as the result of prolonged investigations I had concluded that such waters could be purified either by treatment with metallic copper or with calcium hypochlorite. Copper, however, appears to have a selective action upon bacteria; it may destroy all the typhoid bacilli in a water yet not affect the bacteria of the coli group. Calcium hypochlorite, on the other hand, destroys both with equal ease.

When in Boston, Massachusetts, recently, my friend, Professor Sedgwick, directed my attention to some work which had been done by Dr. Phelps who is engaged in carrying out a long series of experiments for the city of Baltimore, having for their object the sterilisation of the effluent from bacteria beds before allowing it to enter Chesapeake Bay, where there are extensive oyster layings. Dr. Phelps kindly showed me these results which proved that a very small quantity of calcium hypochlorite was capable of producing sterilisation provided the effluent was fairly clear and free from easily oxidisable organic matter, and he hinted that such a method of purification was being considered for a public water-supply. Upon my return I resumed my experiments with calcium hypochlorite, using natural waters, to which the bacillus typhosus and bacillus coli were added, without at the same time introducing an abnormal quantity of organic matter. To my great surprise I then discovered that exceedingly minute quantities of this chemical sufficed for sterilisation—in most cases 1 part of chlorine as hypochlorite to 1 million of water being sufficient —and that the action took place in a very few minutes. By the addition of a little sodium bisulphite at the end of the time required for effecting the destruction of the bacteria the remaining chlorine can be removed and the palatability of the water remains unimpaired. Experiments of a varied character have been made with waters from divers sources, but the following will suffice as showing their scope and the results obtained.

1. To chalk water to which had been added five cubic centimetres of a clear sewage effluent to each litre hypochlorite equivalent to two milligrammes of available chlorine was added and the mixture allowed to stand for 30 minutes. The untreated water contained some thousands of bacteria per cubic centimetre and one cubic centimetre gave acid and gas with bile-salt glucose broth. The treated water caused no growth whatever in the same broth when ten cubic centimetres were added thereto.

2. To the same water was added a filtered dilute broth containing a growth of the typhoid bacillus and an equal quantity of a diluted bile-salt broth containing the bacillus coli. Chlorine in hypochlorite was added, two milligrammes per litre, and allowed to stand for one hour. The colonies from one cubic centimetre of untreated water on malachite green medium exceeded 3000, of which about half appeared to be the bacillus typhosus. Acid and gas were produced by 0·1 cubic centimetre in bile-salt broth. After treatment there was no growth whatever from one cubic centimetre upon the malachite green medium. Neither acid nor gas was produced by the treated water when one, five, ten, and 20 cubic centimetres were added to the bile-salt broth.

3. To water from a rainwater tank mixed with a dilute broth containing the bacillus coli was added chlorine in hypochlorite equivalent to two milligrammes per litre. The excess of hypochlorite was destroyed by sodium thiosulphate before applying bacterial tests. The results were as follows:—

	Min.	Mins.	Mins.	Mins.
Time of action...	1	... 10	... 20	... 30
Colonies from 1 cubic centimetre on agar in 24 hours ...	Thousands	... 3	... 4	... 1

Acid and gas were given by one cubic centimetre of the impure water in bile-salt glucose broth. Neither acid nor gas was produced by the pumped water with 36 cubic centimetres.

4. To ten litres of tap-water + 3 cubic centimetres of a fermenting bile-salt broth chlorine in hypochlorite was added, 1 milligramme per litre. This mixture gave acid and gas in bile-salt glucose broth when 0·1 cubic centimetre was added, and upon agar 1 cubic centimetre gave 3120 colonies in 24 hours.

	Minutes.	Minutes.	Minutes.
Time of action	10	 20	 30
Colonies from 1 cubic centimetre on agar	0	 0	 0

Neither acid nor gas was produced by 36 cubic centimetres of the treated water in bile-salt broth.

5. Repetition of using a soft rainwater instead of tap-water gave identical results. Apparently the water was absolutely sterilised.

6. Water from a well in the new red sandstone infected with bacillus coli. The untreated water gave 2380 colonies on agar plate from 1 cubic centimetre. Acid and gas were produced in bile-salt broth from 0·1 cubic centimetre.

Chlorine in hypochlorite per litre of water.	Duration of action.				
	1 minute.	6 minutes.	12 minutes.	18 minutes.	24 minutes.
0·5 milligramme.	+	+	+	+	+
0·75 "	+	+	+	+	–
1·0 "	+	–	–	–	–

The 1 milligramme Cl per litre water at the end of five minutes gave acid but no gas when 20 cubic centimetres were added to bile-salt broth. After 24 minutes there was no growth whatever, neither acid nor gas being produced from 20 cubic centimetres.

In all these and many other experiments the amount of chlorine (available) in the water was determined. Some failures which occurred in the earlier experiments were found to be due to the fact that the organic matter added had absorbed all the available chlorine, leaving none to act upon the bacteria. As a rule about half the chlorine was used up. In passing it may be remarked that the quantity of chlorine destroyed by a water appears to be a good index of its quality, and experiments bearing upon this point are being undertaken.

From inquiries made at chemical works I find that calcium hypochlorite containing 33 per cent. of available chlorine can be delivered at £15 per ton and sodium bisulphite at £16 per ton. The waters which use up very little chlorine can be sterilised by the use of 3 parts of hypochlorite (= to 1 part of available chlorine) per million, or 30 pounds of hypochlorite per million gallons. The cost, therefore, works out as under: hypochlorite, 4*s.* 5*d.*; bisulphite, 1*s.* 2*d.*; total, 5*s.* 7*d.* per million gallons; or 15,000 gallons for 1*d.*, or 0·067*d.* per 1000 gallons. Waters containing organic matter, such as peaty moorland waters, could probably be sterilised for less than 10*s.* per million gallons.

Further experiments with natural waters from divers sources are being made, but so far no water has been met with which two parts of chlorine per million failed to sterilise. The amount of chemicals added is so small that they do not affect in any way the character of the water. The chlorine and hardness are only increased by a minute fraction of a grain or degree per gallon. There should be no practical difficulty in adding the chemicals and no special apparatus would be required. The hypochlorite would be added as the water entered a tank from a case of Pyonephrosis associated with Insanity. After the nephrectomy there was a rapid disappearance of the *mental symptoms.* 2. Tuberculous epididymitis from a patient aged 70 years. Many years before he had been tapped for ascites.—Mr. W. Thompson showed a Loose Body from the Peritoneum found in the Sac of an Umbilical Hernia. The body contained fæcal concretion.—Mr. Grünbaum showed a section of a Tumour from a case of Neoplastic Diathesis. It was remarkable in showing both carcinoma and sarcoma in close proximity to each other.—Dr. W. H. Maxwell Telling showed a specimen of a Small Traction Diverticulum of the Œsophagus which by perforation had caused gangrene of the lung, suppurative mediastinitis, and pericarditis.—Mr. J. F. Dobson showed a specimen of Endothelioma of the Submaxillary Gland.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Nov. 11th, Dr. W. Milligan, the President, being in the chair.—Professor J. Lorrain Smith discussed the equivocal results which have been obtained in the attempt to study the pathogenic action of bacillus coli by means of (*a*) agglutination, (*b*) opsonic index, and (*c*) bactericidal action of the serum. He pointed out that as yet no clue of this kind had been discovered by means of which the effects in the body of bacillus coli infections might be followed. He then dealt with the loss of bactericidal power in the glandular secretions in cases of bacillus coli infection, (*a*) in the bile, where the bacillus flourishes, (*b*) in the pancreatic juice where the bacilli are as a rule absent even in cases where the liver is invaded, and (*c*) in the intestine, where the normal regulation of bacterial growth is disturbed. He also dealt with the occasional failure of alkaline treatment in pyelitis and suggested that this was probably due to the establishment of necrotic foci in the tissues where the bacilli could grow in spite of the inhibitory influence of the alkali.—Dr. C. Christopher Heywood read a paper on Calmette's Tuberculin Reaction and considered the claims of Calmette that the reaction is easy of application, harmless, and trustworthy. He thought that the test was practically harmless if the strength of the tuberculin used was never greater than 0·1 per cent. Excessive reaction was almost always due to the use of too strong a solution or to repeating the test on the same eye at too short an interval. It was not infrequent, even with a weak solution, to get a phlyctenular conjunctivitis. In considering the trustworthiness of the test he analysed the results of 127 cases. Of these 37 were definitely tuberculous and all except four gave the reaction. The four negative cases died in a short time. There were 20 "doubtful" cases and of these 13 gave a positive and seven a negative reaction; practically all the seven negative cases proved to be not tuberculous. Of the remaining cases (70) thought not to be tuberculous, ten gave a positive and 60 a negative reaction. The ten positive cases included seven cases of chorea and Dr. Heywood's experience was that 50 per cent. of cases of chorea gave a positive reaction. He summed up by saying that he considered the negative reaction to be more trustworthy than the positive.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 18th, Dr. P. Boobbyer, the President, being in the chair.—A motion, proposed by Dr. A. C. Reid and seconded by Dr. W. Hunter, earnestly requesting the corporation of Nottingham to make provision for the erection and maintenance of a municipal crematorium in the future, was agreed to by a large majority.—Mr. W. Morley Willis, in a paper entitled "The Surgeon's Night-bell," alluded to some of the emergencies which might need immediate operation at any hour. In the case of perforated gastric ulcers no one factor had such a favourable influence on operation as early diagnosis and immediate resort to it. Reviews and Notices of Books.

Squire's Companion to the British Pharmacopœia. By PETE WYATT SQUIRE. Eighteenth edition. London: J. & A Churchill. 1908. Pp. 1459. Price 14*s*. net.

To give its full and perfectly justifiable title this work i a companion to the latest edition of the British Pharmacopœia, comparing the strength of the various preparation in that official work with those of the United States an other pharmacopœias, to which are added preparations whic are not official, together with practical hints on prescribing This, the eighteenth edition, has been demanded in vie of the extraordinary advances which have been made i chemistry, pharmacology, and pharmacy during th last decade. Splendidly as the "Companion" ha served in the past so is it calculated to serv equally in the future, for no pains have been spared t visit to me. She complained of no bladder or rectal symptom. With regard to the physical signs, palpation of the abdomen revealed nothing, but the patient kept her abdominal wall rather rigid. The cervix uteri was rather low and was located towards the left wall of the pelvis. The body of the uterus could not be differentiated. In Douglas's pouch and the right quarter of the pelvis was felt a small, firm, and rather convoluted swelling of the consistence of old blood clot.

Operation was performed on Oct. 5th. I opened the abdomen. There was free fluid blood in the general peritoneum which had escaped from the fimbriated extremity of the right tube. The distal end of the right Fallopian tube was the seat of the gestation sac.

PATHOLOGICAL SECTION.

Action of Splenotoxic and Hæmolytic Sera.—Idiopathic Dilatation of the Bladder.—Mode of Action of Gastrotoxic Serum and the Healing of Gastrotoxic Ulcers.

A MEETING of this section was held on Nov. 17th, Mr. S. G. SHATTOCK, the President, being in the chair.

Mr. L. S. DUDGEON, Dr. P. N. PANTON, and Dr. E. A. ROSS communicated a paper on the Action of Splenotoxic and Hæmolytic Sera on the Blood and Tissues. Their experiments were undertaken for the purpose of determining whether it would be possible to produce a splenotoxic serum possessing specific properties, or whether the action of the serum would be on the lymphoid tissue in general, or whether the results obtained were due to the hæmolytic property of the serum. The investigation was further extended to the action of the splenotoxic and hæmolytic sera on the blood and tissue with special reference to the production of fatty degeneration, cell necrosis, and the formation of "hæmolymph glands." They immunised three series of rabbits: (1) with splenic extracts; (2) with unwashed blood corpuscles; and (3) with washed corpuscles obtained from guinea-pigs. The immune sera when injected into guinea-pigs gave results which might be regarded as almost identical, the only difference being that the hæmolytic sera were usually slightly more potent. Another series of rabbits were inoculated with the unwashed blood corpuscles of cats and splenic extracts freed from blood by an elaborate process of washing. The effects resulting from the injection of the splenotoxic and hæmolytic sera were as a rule the death of the animal within 24 hours with small hæmorrhages chiefly into the peritoneum and mesentery, marked swelling and congestion of the spleen, the colour of which was almost jet black, while the remaining viscera were abnormally pallid. In the mesentery dark red glands were found and occasionally similar glands were met with in the groin. The immune sera thus obtained produced changes in the tissues of animals of almost similar character, only they were more pronounced. The fat was of a primrose yellow colour and the viscera and conjunctivæ had a marked "icteroid" tinge. The urine contained a large amount of blood and albumin but no casts and the urine and blood serum were free from bile pigment. The chief microscopical changes consisted of enormous distension of the sinuses of the spleen with red blood corpuscles at the expense of the lymphoid tissue, leaving the Malpighian corpuscles comparatively unaltered and inducing in the endothelial cells a high degree of phagocytosis for erythrocytes and blood pigment. In the affected lymph glands similar histological appearances to those observed in the spleen, that is to say, so-called hæmolymph glands, were noted. There was widespread necrosis of epithelial cells, particularly in the liver and kidney, and extreme fatty degeneration occurred in the same viscera, but, unlike diphtheritic toxin, spared the heart muscle and diaphragm. When the immune serum was heated or saturated with suitable red cells in vitro the final results obtained were similar to those produced by the untreated serum. With the immune serum obtained from one specimen of animal by inoculating with the tissues of another species and then injected into a third species no abnormal effect was produced.

The PRESIDENT exhibited a Dilated and Hypertrophied Bladder with Double Hydronephrosis from a man who had never suffered from any urinary symptoms, in whom there was no enlargement of any part of the prostate, and whose urethra admitted the passage of a catheter without difficulty. He used the term idiopathic in the way in which it was used in the case of the colon, œsophagus, or stomach, in which similar dilatation and hypertrophy occurred; and of these conditions he gave different tentative explanations. In the case of the pelvic colon the dilatation usually commenced shortly after birth. It was a significant fact that in the case of the bladder dilatation without recognisable cause had also been observed in infancy and in the newly born child, one excellent example of the latter being in the Museum of the Royal College of Surgeons of England. The dilatation might be due to incoördination between the contraction of the detrusor and the dilatation of the sphincter; and there was the theoretical possibility, also, of a hypoæsthetic state of the mucosa whereby the reflex of micturition would not arise until the viscus had reached what in normal circumstances would be an abnormal degree of fulness. Experiments made by Dr. T. G. Brodie and himself showed that in the cat, if the vesical mucosa was anæsthetised by means of cocaine, on the bladder being filled with warm salt solution micturition was abolished, the organ becoming markedly distended. This result indicated that the reflex of micturition was initiated by the tension of the vesical mucosa—i.e., the contraction of the detrusor and the associated dilatation of the sphincter. Whether anæsthesia or hypoæsthesia of mucous membranes occurred as a hysterical phenomenon was a subject that would repay investigation.

Dr. CHARLES BOLTON read a paper on the Mode of Action of Gastrotoxic Serum and the Healing of Gastrotoxic Ulcers. He said that the gastrotoxic serum referred to was prepared by immunising the rabbit with guinea-pig's gastric cells. The action of the serum was manifested in two directions: (1) by the production of general symptoms of intoxication; and (2) by the formation of patches of necrosis in the mucous membrane of the stomach which developed into ulcers. It was proved that the serum acted directly upon the gastric cells and not primarily upon the capillary wall leading to hæmorrhage, because if the gastric juice were neutralised with an alkali at the time that the serum was injected no lesions resulted. Neutralisation of the gastric juice would, of course, not prevent a hæmorrhage occurring. The actual necrosis of the mucous membrane was produced by the gastric juice, because no microscopic change could be seen in the cells when the gastric juice was put out of action. It appeared, therefore, that some pathological change was produced in the cells whereby they were rendered susceptible to digestion by the gastric juice. That pathological change was probably a devitalisation of the cell and not the removal of any specific resisting power possessed by the cells, because other poisons, hepatotoxin, enterotoxin, and hæmolysin, were able to produce an action on the gastric cells of precisely the same nature only to a much less extent. Those two observations, the initiation of self-digestion resulting from the circulation of a poison in the blood and the non-specificity of the poison, were considered of great importance because they raised the question whether there might not be many endogenous and also exogenous poisons (bacterial or otherwise) which by their action on the gastric cells could bring about self-digestion. It was shown that certain protoplasmic poisons in solutions, which were of themselves inert, were able to increase the lesions produced by gastrotoxin if they were introduced into the stomach when the latter was injected into the animal. Such solutions were hydrochloric acid above 0·3 per cent., sulphuric acid above 0·5, acetic acid above 0·5, and lactic acid above 2 per cent. It was therefore considered probable that hyperacidity of the gastric juice or the taking of inert solutions of certain substances by the mouth (e.g., vinegar) could in the presence of a devitalising agent in the blood bring about self-digestion. The gastric lesions produced by hepatotoxin, enterotoxin, and hæmolysin were shown to be increased by the acids also. It was considered that no cytotoxin was specific, each acting especially upon the cells against which sequence of symptoms are traced in a number of cases, and the relation between the temperature and the number of trypanosomes in the patient's blood is demonstrated by means of several excellent charts, by which it is made clear that as a rule these vary in direct proportion to each other; and the greater the number of the parasites the higher the temperature. To this rule, however, there are striking exceptions towards the fatal termination of an attack, when the temperature is sometimes subnormal, even although the blood swarms with trypanosomes.

As regards prophylactic and curative measures the authors have no new suggestions to make. The disease is endemic in the Malay States and the authors suggest the slaughter of all animals found to be affected and also of all animals emaciated without any apparent reason. They recommend that herding of cattle in large numbers, especially near jungle, should be avoided and they advise the detention of all imported animals at the port of arrival until such time as they have been examined. Treatment by atoxyl has been tried in several cases but the good results obtained in some were only temporary, death being the usual ending. No better results were obtained with mercuric chloride and tartarated antimony. Some excellent plates, prepared from photographs, illustrate the morphology of the trypanosoma Evansi.

The Government entomologist, Mr. H. C. Pratt, has contributed an article on the Distribution of Certain Species of Biting Flies in the Federated Malay States, and this, together with a map of the country, completes this interesting little scientific brochure which is worth the attention of all students of tropical medicine, since the conclusions arrived at here may serve to throw further light on human trypanosomiasis. Tropical medicine is indebted to the conjoint authors for their endeavours to elucidate further the phenomena of this serious disease. The printers have done their work well; the printing and binding leave nothing to be desired.

A System of Syphilis. In Six Volumes. Edited by D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., and J. KEOGH MURPHY, M.D., M.C. Cantab., F.R.C.S. Eng. With an Introduction by SIR JONATHAN HUTCHINSON, F.R.S. Vol. I. With 68 plates. London: Hodder and Stoughton and Henry Frowde. 1908. Pp. xxxv.-380. Price £2 2*s.* net per volume.

THE appearance of a work on syphilis containing among the names of the contributors those of Professor Elie Metchnikoff and Sir Jonathan Hutchinson cannot fail to excite the interest and to arouse the expectation of the reader. We may say at once that in the first volume of this work such expectations will be more than fulfilled. The book is one of great merit and the editors are to be congratulated cordially on this exceedingly good beginning to their enterprise. If the remaining volumes maintain the high level of excellence of the first, the whole will form a treatise on syphilis of the utmost value and importance. The sections of most interest in the present volume are the introduction by Sir Jonathan Hutchinson and the account, as absorbing as a romance, of the microbiology of syphilis written by Professor Metchnikoff and translated with much success by one of the editors, Mr. Keogh Murphy. In his introduction Sir Jonathan Hutchinson surveys the whole field of syphilis in the light of the most recent work and especially of the discovery of the spirochæta pallida. At the same time he utters a wise and weighty warning to the many workers in the new field of experimental study which has been opened up by the discovery of the specific organism of syphilis and the fact of its communicability by inoculation to some of the higher apes, that their inferences should not be hastily accepted without clear proof and that they should remember the disastrous results of the conclusion of John Hunter, based on erroneous experiments, that gonorrhœa and syphilis were caused by the same poison.

It is only necessary to read the series of questions propounded by the writer of this essay to realise how many and important are the problems connected with this disease on which our knowledge is at the present time of the very scantiest description. Possibly in the course of time the stimulus which the recent discoveries in this field of medicine have given to further investigations may lead to the elucidation of some at any rate of these perplexing questions.

The first chapter in this volume is one on the history of syphilis by the well-known authority on this subject, Dr. Iwan Bloch. He demonstrates beyond the possibility of doubt that the last decade of the fifteenth century—particularly the years 1493-1500—was the time when syphilis first appeared in the Old World. Further than this, he shows certainly that syphilis was unknown in Europe before the year 1493 and that its home was the island of Española or Haiti, whence the crew of Columbus brought it after the latter's first voyage. The various arguments as to the pre-Columbian origin of syphilis are considered fully and refuted, and this is followed by a short account of the early and later history of syphilis in Europe.

Professor Metchnikoff's article contains, as we have said, a most absorbing account of the work done in the search for the specific organism of syphilis ending in the brilliant discovery by the late Fritz Schaudinn—foreshadowed, as he shows, by the work of the French microscopist, Donné, as early as the year 1837—of the spirochæta pallida and the proof of its etiological relation to all the lesions of this protean disease. Professor Metchnikoff's generous recognition of the brilliant work done by Schaudinn is reflected in the happy inspiration of the editors who have dedicated their work to his memory and to the trio of distinguished syphilographers, still with us, Fournier, Hoffmann, and Hutchinson.

The section on the general pathology of syphilis is contributed by Dr. F. W. Andrewes and we can pay it no higher compliment than to say that it is quite as good as the chapters which precede it. From his very large experience Colonel F. J. Lambkin, R.A.M.C., writes with authority on the subject of the primary lesion and early secondary symptoms as seen in the male. In the very excellent tables which he gives to render the diagnosis of a chancre easier we must confess that we think the use of the term chancroid liable to mislead, especially as the next table is headed non-syphilitic ulceration, which, we infer, may be of the same character—namely, chancroid. Does Colonel Lambkin mean by this term a mixed chancre or the ulcus molle, the soft chancre, or what Sir Jonathan Hutchinson suggests had much better be called the non-indurated ulcer? The confusion is likely to be even worse if the term chancroid is to be used in reference to the very atypical primary lesions so often met with in women.

The early manifestations in the female sex are described by Dr. Arthur Shillitoe who calls special attention to the fact that often no obvious primary lesion is to be found even after the most careful examination and to the interesting question of a pigmentary syphilide of the neck as an early secondary symptom. The final chapter on congenital syphilis is from the pen of Dr. G. F. Still and contains a most complete account of this important phase of the disease.

The plates, 68 in number, are very good and we may call special attention to the direct colour photographs now used for the first time to illustrate clinical conditions and for which the editors acknowledge their indebtedness to Mr. Tubbs and Dr. Arnold Moritz. The printing and type are three symptoms, and the PRESIDENT considered that to deserve the name there must be an intimate relation between the nerves and the tumours.—Dr. FENTON, in reply, said that pigmentation appeared after the nodules had formed.

Mr. T. H. OPENSHAW showed a case of extreme Coxa Vara of the Left Leg, of traumatic origin. He also exhibited a case of Ununited Intracapsular Fracture of the Neck of the Femur, treated by screwing, with union. The patient could now stand on his right leg without pain and could walk all day long without fatigue.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Cæsarean Section and Total Abdominal Hysterectomy.—Cancer of the Cervix Uteri.—Hysterectomy for Fibro-myoma of the Uterus.

A MEETING of this section was held on Nov. 12th, Dr. HERBERT R. SPENCER, the President, being in the chair.

The PRESIDENT read a short communication on Cæsarean Section and Total Abdominal Hysterectomy for retroflexion of the uterus at term by fibro-myoma adherent in Douglas's pouch. The patient was a primigravida, aged 38 years, and was admitted into University College Hospital. She was in labour and the pelvis was found to be occupied by a hard, fixed tumour of the size of the fist. On abdominal examination the lower part of the uterus was noticed to bulge forward to an unusual degree and appeared very thin. The child was removed by Cæsarean section but was found to be dead. The whole uterus and the tumour, which was fixed by adhesions, were removed by Doyen's method. The peritoneum was completely closed by a silk purse-string suture. The subsequent examination of the specimen showed that the uterus was retroflexed almost to a right angle, the angle of the canal being a sharp spur formed by the posterior wall at the internal os. The anterior wall had been greatly stretched and the lower segment was only seven millimetres thick. Retroflexion of the uterus at term produced by an adherent fibro-myoma was rare. Cases recorded by Herman and Varnier and Delbet were referred to. With regard to the diagnosis between adherent fibro-myoma and ovarian tumour, the presence of other tumours in the wall of the uterus would aid in the diagnosis, but the President was disposed to attach considerable value to the bulging and thinning of the lower segment as evidence that the tumour was a uterine fibroid and that the uterus was retroflexed. Cæsarean section followed by total abdominal hysterectomy was the treatment required.—Dr. W. RIVERS POLLOCK referred to a successful case of his own where he had performed Cæsarean hysterectomy for fibroids obstructing labour.—Dr. AMAND J. M. ROUTH congratulated the President on his treatment of this case.

Dr. C. E. PURSLOW read a short communication on a case of Cancer of the Cervix Uteri, with unusual microscopical appearances, in a patient, aged 21 years.

Mrs. M. A. D. SCHARLIEB read a paper entitled "Notes on a further 100 Cases of Hysterectomy for Fibro-myoma of the Uterus." The degenerations and complications were especially dealt with and illustrated by tables. At the end of the paper Mrs. Scharlieb pointed out that in this second hundred series of operations for fibroids none were done by the vaginal route. Pan-hysterectomy was done 42 times and she considered this the ideal operation.—Mr. ALBAN H. G. DORAN considered that this brilliant series showed that a patient might be relieved at very little risk of the mental distress caused by the presence of a uterine fibroid. At the same time he thought that many of the cases included in the tables were much too recent. Removal of a fibroid uterus was quite different from ovariotomy; an after-history of at least two years was necessary before the full benefits of the hysterectomy could be determined. He also regretted that the tables did not include a column noting the treatment of the ovaries, as well as a column for the after history, as in his own series brought before the Obstetrical Society just three years ago. His experience was identical with that of Lucas-Championnière who recently declared that an artificial menopause was a very grave matter and that year by year he spared more and more ovaries when performing hysterectomy.—Dr. AMAND ROUTH joined his congratulations to those of Mr. Doran and would merely criticise one point in Mrs. Scharlieb's paper. Would it not have been more correct to place the occurrence of carcinoma of the endometrium in the "Complication" rather than in the "Degeneration" column? Carcinoma uteri—whether of the body or cervix—was surely a complication and could not be grouped with necrobiosis, sloughing, or even with that variety of sarcoma which was truly a degenerative change. He noticed that Mrs. Scharlieb had not removed the cervix in the second case of carcinoma and fibroids (No. 152), but he presumed the cancer was not diagnosed till afterwards. As the patient was operated on in 1905 he would like to hear if recurrence had yet taken place.—The PRESIDENT and Dr. MACNAUGHTON-JONES also complimented Mrs. Scharlieb on the low rate of mortality in her series of cases.

MEDICAL SOCIETY OF LONDON.

Recurrence after the Operation for Radical Cure of Inguinal Hernia.—Two Cases of Hæmorrhage into the Testicle of Doubtful Origin.

A MEETING of this society was held on Nov. 23rd, Mr. C. B. LOCKWOOD, the President, being in the chair.

Mr. W. H. BATTLE read a paper on Recurrence after the Operation for Radical Cure of Inguinal Hernia. He said that there were 35 operations recorded in his case-books which had been performed for recurrent inguinal hernia, and of those 34 were required on male subjects and only one on a female patient. These were almost equally divided between the right and left sides. The general impression was that suppuration was the most frequent cause for the return of a hernia after attempted radical cure. In only four of these 35 operations was there clear evidence that suppuration had followed the original operation, in nine it was not possible to come to a conclusion on that point, whilst in 22 there was no doubt that primary union had been obtained. That was all the more noteworthy because all cases presenting the slightest trace of pus were put down under that heading, no matter how slight the amount, whether merely a stitch abscess or a more general suppuration. In a series of 107 recurrences after operation for hernia reported from St. Thomas's Hospital the cases in which it was recorded that there had been suppuration during the after-treatment only numbered 22. That hardly bore out the statement of Jacobson, "In nearly all the relapsed cases some suppuration had occurred and that was no doubt the main cause of the relapse." There was no doubt that suppuration sometimes acted disastrously by loosening or destroying perishable sutures and rendering others a source of continued irritation; still, most of them had probably seen instances in which a satisfactory result had been obtained in spite of their fears—the formation of a large amount of scar tissue binding the parts firmly together. If a hernia was going to relapse the return would take place within a few months of the date of the first operation. In the series of 35, the period of time varied considerably; in one it happened almost immediately, whilst it was found within 12 months in 16 patients, between one and two years in 11, and more than two years in the remainder—eight in number. In other words, it returned within 12 months in nearly half the cases. Inadequate operation might leave the patient exposed to the formation of another kind of hernia on the same side, and until a second operation was performed the nature of that hernia would not be known. Obliteration of the sac was undoubtedly an important part of the process of radical cure, and the peritoneum must be shut off smoothly at the internal ring, so that there was no pouching left into which omentum could force its way. He was of opinion that in some of the instances in which recurrence took place at an early date there had been a slipping of the ligature after the sac had been cut off, and that the omentum had found the weak spot and passed along the cord. The importance of the presence of the cord was fully recognised by operators, for all would admit that recurrence was hardly known in the female. In addition to the mere presence of the cord, which had a tendency to drag on the inner margin of the internal ring and acted as a guide to the descent of a peritoneal pouch, it was possible that during the application of the ligature, in the neck of the sac, some of the cord might be included in the ligature and that in replacement of parts before the suturing of the wall of the canal that attachment might be pulled upon and a small pouch formed from the very first. Or again, the dragging of the testis in normal movement of the body might bring that point down at a later sequence of symptoms are traced in a number of cases, and the relation between the temperature and the number of trypanosomes in the patient's blood is demonstrated by means of several excellent charts, by which it is made clear that as a rule these vary in direct proportion to each other; and the greater the number of the parasites the higher the temperature. To this rule, however, there are striking exceptions towards the fatal termination of an attack, when the temperature is sometimes subnormal, even although the blood swarms with trypanosomes.

As regards prophylactic and curative measures the authors have no new suggestions to make. The disease is endemic in the Malay States and the authors suggest the slaughter of all animals found to be affected and also of all animals emaciated without any apparent reason. They recommend that herding of cattle in large numbers, especially near jungle, should be avoided and they advise the detention of all imported animals at the port of arrival until such time as they have been examined. Treatment by atoxyl has been tried in several cases but the good results obtained in some were only temporary, death being the usual ending. No better results were obtained with mercuric chloride and tartarated antimony. Some excellent plates, prepared from photographs, illustrate the morphology of the trypanosoma Evansi.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Baths and Mineral Waters.—Exhibition of Case.

A MEETING of this section was held on Nov. 6th, Dr. W. G. SMITH, the President, being in the chair.

The PRESIDENT gave an address on Baths and Mineral Waters, and some Fallacies connected Therewith. After some general remarks and a brief reference to radio-activity as a possible factor of efficiency, he drew attention to the chemical analyses of mineral waters and the misleading way in which the analytical figures were often expressed. Chemical analysis of a water should simply state the respective amounts of each acid, and basic radicle, i.e., of each ion, for no one knew or could tell how these were severally distributed as salts. The subjects of ionisation and of osmosis were touched upon. Did they know anything of the physiological action of pure water? Nothing whatever. Pure water was extremely difficult to prepare, and the modifying influence of even the slightest salinity was strikingly shown by observations of the electrical conductivity of water, which depended upon the ions present in solution. The purest water in nature was that from molten natural ice. But the purer the water was the more injurious was it to the tissues and hence the evil effects of drinking snow or glacier water. The essential factors of the external or local action of baths were two: (1) temperature; and (2) stimulation of the sensory surface of the skin. Soot baths, mud and peat baths were to ordinary waters what brown bread was to white bread; they tickled more. In explanation of the benefits which undoubtedly accrued to the crowds who flocked to baths and spas, reference was made to the late Mr. Ernest Hart's acute observations published in the *British Medical Journal* in 1887 and entitled "Spray from the Carlsbad Sprudel," and which were of general application. A Carlsbad (or other) "cure" was a very complex therapeutic agent. It was a rest cure, a diet cure, an air cure, a music cure, an exercise cure, a mind cure, and a body cure. There were very few forms of gastric, intestinal, renal, and nervous cases which were not capable of being benefited by such a treatment, even if that were not at all mineralised. In default of these pleasant and essential accessories it was vain to expect similar good results from waters alone if they were situated in places where these collateral advantages were denied by nature, by poverty, or by other adverse conditions.—Dr. JAMES LITTLE said that in selecting a mineral water for a patient the medical man had to consider the characteristics of the patient, the climate of the place to which he was going, the bathing and drinking facilities, and the social amenities of the place, and the medical practitioner under whose care the patient was going. He did not think that mineral waters did as much good nowadays as 50 years ago, because the patients of former times had realised incomes and could go away without any mental disturbance, but patients now worked up to 2 o'clock in the morning arranging their business, and then rushed off and drank more than they were ordered, and so got little benefit. A patient with organic disease who was sent to mineral waters had usually incalculable injury done to him, but if the disturbance was only functional real benefit would be derived. He thought that the reputation of many watering places depended on the ability of the local medical men.

Dr. P. DEMPSEY exhibited a case of Mycosis Fungoides in a man, aged 62 years, by occupation a small farmer. Up to five or six years ago he had enjoyed perfect health. There was nothing peculiar in his family history. At first a rash appeared on his back and remained for a year. It then invaded his chest and spread to his legs. It became indurated in places and was also scaly. One and a half years ago a small lump appeared on his shoulder and increased very much in superficial extent but not in height. Other lumps followed. Some disappeared spontaneously after a few months. The general health did not suffer, despite the extent of, and the irritation caused by, the disease, but the patient thought himself less able for hard work. The case was being treated with the x rays and had so far had four exposures.—The PRESIDENT said that the disease was extremely rare in Ireland. He had seen no case for ten years. The name "mycosis fungoides" had been introduced into the nomenclature by Alibert 100 years ago, and modern pathologists had not yet been able to give it a definite place.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — A meeting of this society was held on Nov. 11th, Dr. J. Michell Clarke, the President, being in the chair.—Dr. E. C. Williams showed a child, aged two years, who had recently recovered from Basic Meningitis with Temporary Amaurosis. During the course of the disease there had been complete loss of sensibility to light without any visible change in the ophthalmoscopic appearances. The case had markedly benefited from small doses of liquor morphinæ administered regularly. Recovery had left the child unable to walk or to talk, but the vision was apparently good. He regarded the case as an example of that form of posterior basic meningitis during the course of which the child appeared to lose his sight without any discoverable ophthalmoscopic change. The children at a later date often regained both their sight and health. They were usually below two years of age.—Mr. H. F. Mole, in discussing the case, suggested that possibly the child was deaf as the result of the meningitis and hence was unable to regain the lost art of speech.—Dr. Bertram M. H. Rogers said that his experience did not agree with that of Hutchison (previously cited) that about half of the cases of posterior basic meningitis made a more or less complete recovery.—Mr. Cyril H. Walker suggested that the amaurosis was due possibly to a retro-ocular neuritis; the loss of pupil reflex to light pointed to this conclusion.—Dr. F. H. Edgeworth referred to the treatment of this disease by serum, which had reduced the mortality in the Belfast epidemic 30 per cent., questioning whether the same serum would prove efficacious in the sporadic cases. The meningococcus in the two varieties, although morphologically and culturally identical, gave different agglutination and opsonic reactions, so that it was probable that the serum of the epidemic variety would fail with the sporadic. He had seen in three or four cases very good results from the morphine treatment advocated by Barr.—Professor I. Walker Hall thought that admirable as Flexner's serum had proved in some epidemics the correct plan to follow was that of preparing a serum from individual cases or epidemics wherever practicable.—Dr. P. Watson Williams showed a patient upon whom he had operated for Suppuration in the Frontal Sinus by the osteoplastic flap method. The result had been excellent not only from the point of view of relieving the symptoms but also as regards the cosmetic effect, the scar being barely visible.—Dr. J. Lacy Firth agreed that the operation was a very good one; he had found that it gave the best access to the ethmoidal region and left no deformity.—Mr. James Taylor read a paper on Some Fallacies in Skiagrams, which he illustrated by actual mistakes, showing how a fracture might escape notice completely if photographed in a single plane. Tuberculous masses in the kidney simulating calculi and other examples were shown.—Dr. James Swain insisted on the importance of such facts being published from the medico-legal aspect. He said that frequently the result of treatment of a fracture looked bad in a skiagram, while clincally no inconvenience was experienced.—Dr. Watson Williams emphasised the value of stereoscopic skiagram which cleared up many difficulties.—Dr. G. E. Bowker spoke of the misleading appearance of exostoses in some cases of suspected injury.—Mr. E. W. Hey Groves, referring to the transparency of callus, said that the patients might, by seeing a skiagram, be led to suppose that there was no union between the ends of a fractured bone.—Mr. A. L. Flemming said that during the South African war he had come to realise the value of stereoscopic skiagrams.—Dr. H. L. Ormerod read notes of a case of a Double Monster. In a full-time birth in a primipara, aged 25 years, the two embryos were joined by a broad isthmus from the manubrium sterni to the umbilicus (thoracopagus); their total weight was 11¼ pounds; the sex was female. When he arrived the mother had been in labour 18 hours, the waters had broken one hour previously, the pains were vigorous, and the abdomen was unduly prominent. The cervix was well dilated and the presentation was a third vertex; progress had come to a standstill. The head was delivered with forceps but the body would not follow. Vaginal examination revealed some abnormal prominence over the chest, in compiling a work which has been much needed for very many years past; it cannot properly be termed a public officer's *vade mecum* because of its size but it may certainly be regarded as a work of reference of the greatest utility.

Verhandlungen des Vereins Süddeutschen Laryngologischen, 1908. (*Proceedings of the Society of South German Laryngologists.*) Würzburg: A. Stuber. Price 2 marks.—There are ten papers reported in this issue of the Proceedings of the South German Laryngological Society. One by Brüning on the Lighting Principles of Endoscopic Tubes is of very great interest, as it is beautifully illustrated and will be found of undoubted benefit to those laryngologists who are using these instruments which now appear to have arrived nearly at perfection. This is followed by a paper by Körner on the Clinical Causes of Ocular Paralyses and Paralysis of the Recurrent Nerve; Goris contributes a short note on the Radical Removal of Commencing Nasal Sarcomata; Guyot has a paper of rather greater length on Tuberculous Tumours of the Nose and Naso-pharynx; and Manasse a short paper on the Pathology and Therapy of Malignant Diseases of the Antrum of Highmore; whilst Meyer showed preparations from a case of Leukæmic Affection of the Pharynx. A case was shown by Kante of a Tumour of the Pontine Angle of the Cerebellum, with discharge of cerebro-spinal fluid from the nose, which is of interest when we remember the interesting case similar in some respects to this one, which was reported by Dr. StClair Thomson. Nager contributes a paper on Tumours of the Naso-pharynx; Schaefer describes a stool for Laryngoscopy and other examinations; and Jurasz demonstrates an Unusual Anomaly of the Naso-pharynx. The articles are all very short but they are extremely well written and edited.

Die Lehre von der Intubation. (*The Study of Intubation.*) Von Professor Dr. J. VON BOKAY, Direktor des "Stefanie" Kinderspitals zu Budapest; Ehrenmitglied der Moskauer kinderärztlicher Gesellschaft; korrespondierendes Mitglied der Société de Pédiatrie in Paris und der Aertzlicher Akademie in Rom. With 113 Illustrations in the Text and 2 Plates. Leipsic: F. C. W. Vogel. 1808. Pp. 250. Price 10 Marks.—At first sight it would appear difficult, without undue padding, to produce a book of this large size on the subject of intubation, but when we come to examine critically the result of Professor Bokay's labour a very different impression is derived, for not only is the whole history from O'Dwyer's original communication, just ten years ago, given in detail, but also practically all the literature on the subject which has appeared in the medical press in any language has been brought under contribution. The instruments, from their earliest form to the present, are accurately described and faithfully reproduced. The value of intubation in other diseases besides diphtheria, such as chronic subglottic hypertrophy, scleroma laryngis, laryngeal papillomata and stenosis, is carefully considered. The *pros* and *cons* for intubation *versus* tracheotomy are likewise weighed with judicial impartiality; finally there is what it would be imagined is a most complete bibliography of the literature, comprising some 30 pages. As a work of reference on intubation the book cannot well be surpassed and must inevitably prove extremely valuable to all future writers on, and students of, the subject.

JOURNALS AND MAGAZINES.

Ophthalmology. Edited by H. V. WURDEMANN, M.D., of Milwaukee; Assistant Editor, G. I. HOGUE, M.D. Vol. V., No. 1. October, 1908. Issued quarterly. Editorial and Publishing Offices, 105, Grand-avenue, Milwaukee, Wisconsin, U.S.A. Price per number, 6*s.*; per annum £1 1*s.*—In addition to numerous abstracts from the current literature on ophthalmology and reviews of recently published works on that subject this number contains the following original articles: 1. Artificial Illumination of Schoolrooms, by Myles Standish, M.D., of Boston. In this article the arrangements adopted in the Boston schools with tungsten lamps with Zalinsky shades are described. 2. The Treatment of Chronic Simple Glaucoma, by C. A. Veasy, A.M., M.D., of Philadelphia, with numerous diagrams in the text. The author shows that the meiotic treatment often fails and gives suggestions for the adoption of operative measures. 3. Glaucoma following Secondary Cataract (Capsular) Operation, with a report of three cases, by Frederick E. Cheney, M.D., of Boston. 4. Microphthalmia, by H. H. B. Cunningham, M.D. Brux., F.R.C.S. Irel., M.R.C.S. Eng., of Belfast. 5. Case of Papilloma of the Cornea, by Eugene Smith, M.D., of Detroit, Michigan, with a drawing. 6. Extirpation of the Lacrymal Sac, When and How? by Jesse S. Wyler, A.B., M.D., of Cincinnati, Ohio. The operation is especially applicable to cases of ulcus serpens. 7. The Ocular Symptoms of Ethmoidal Disease, by Frederick Krauss, M.D., of Philadelphia. 8. A Solution of Dr. George T. Stevens's New Phenomenon of Colour Conversion, by E. E. Blaauw, M.D., of Buffalo, New York.

Annals of Ophthalmology. Edited by WILLIAM T. SHOEMAKER, M.D., of Philadelphia, and C. W. PARKER, M.D., of St. Louis. Vol. XVI., Nos. 3 and 4. St. Louis, Missouri, U.S.A.: Jones H. Parker. Price, with "Annals of Otology," $7.00.—These numbers contain a biographical sketch of W. Thompson, M.D., of Philadelphia, an eminent American ophthalmic surgeon; The Amplitude of Accommodation at Different Periods of Life and its Relation to Eye Strain, by Edward Jackson, M.D., of Denver, Colorado; Anisometropia, by W. Bruner, M.D., of Cleveland, Ohio; Double Perforation of the Eyeball by Metallic Bodies, by Edward Adams Shumway, M.D., of Philadelphia; History of a Case of Subretinal Cysticercus by Fernando Lopez, M.D., of City of Mexico; Observations on the Motais Operation for Ptosis, by W. T. Shoemaker, M.D., of Philadelphia; and there are also numerous abstracts from the ophthalmic literature of England and the continent.

The Edinburgh Medical Journal.—The most interesting paper in the November number of this journal is perhaps a post-graduate lecture by Sir Alexander Russell Simpson on Uterine Fibroids, in which a historical sketch is given of the gradual progress of gynæcology in operative measures for uterine conditions. The introductory address of Mr. F. M. Caird on the Evolution of Surgery in Edinburgh is also historical in type. Dr. D. P. D. Wilkie writes on vaccine treatment for mixed infection in tuberculous disease, from which he has obtained good results in the direction both of prophylaxis before operation and of cure of post-operative fistulas. Sir George Thomas Beatson records a case of rapidly growing Fibro-adenoma of the Mamma; and Mr. Alexander Don one of Congenital Diaphragmatic Hernia in an old man.

The Dublin Journal of Medical Science.—A portrait of the late Sir Arthur Vernon Macan forms the frontispiece of the November issue of this magazine and a paper from his pen on the Operative Treatment of Puerperal Fever constitutes the main original article. He notes the brilliant results that have been obtained in cases of threatened or early peritonitis from the procedure of separating the uterus as far as possible from its surroundings, administering large doses of iodine, and stimulating the action of the kidneys. Ligature or removal of infected veins and hysterectomy are also discussed. Dr. Robert J. Rowlette contributes a pathological report of the Rotunda Hospital for the year ending on Oct. 31st, 1907.

produce punched-out sores. The note was also discussed by the President, Dr. F. W. B. Young, Dr. E. T. Davies, Dr. S. M. Whittaker, and Dr. J. Lloyd Roberts.—Mr. G. P. Newbolt read a paper on *Suprapubic Prostatectomy.* He advised operation in the following conditions: (1) complete retention and catheter life in otherwise healthy men; (2) frequent micturition rendering life unbearable and coming on at an early age; (3) profuse hæmorrhage from the prostate and recurring at frequent intervals; and (4) occasional retention with difficulty in the passage of, or inability to pass, a catheter. He did not advocate the operation in malignant disease. He considered that any after-trouble in the way of stricture was due to removal of the membranous urethra.—Mr. F. T. Paul considered that the operation was very remarkable in the results derived from it. In performing the operation he made as small a wound in the bladder as he could work with. He commenced enucleation within the neck of the bladder. If hæmorrhage occurred after the operation he removed the tube when, as a rule, the bleeding would stop. He never operated in cases where he considered the enlargement to be malignant.—Mr. W. Thelwall Thomas believed that the mortality would in the future be lessened by operating earlier in the condition. He always made a curved transverse incision and employed air distension of the bladder. Recently he had employed perineal drainage, as suggested by Lynn Thomas, and was very pleased with this improved method.—*The paper was also discussed by the* President, Dr. Davies, Mr. D. Douglas-Crawford, and Mr. R. A. Bickersteth.

Society of Medical Officers of Health.—A meeting of this society was held on Nov. 13th. Mr. Edward Sergeant delivered his presidential address upon County Health Administration. After giving a short historical account of the evolution of the county medical officer of health, the President dealt with the various public health matters with which county councils are concerned. He described at some length the powers possessed by county councils with respect to the prevention of the pollution of [illegible] and pointed out that certain trade pollutions, such as [illegible] derived from dye, print, and bleach works, chemical [illegible], tanneries, paper-making, woollen works, and silk [illegible], were amenable to chemical and mechanical remedies which might be applied without interfering with manufacturing interests. He instanced the "Magma" process for recovering crude oil from the soap-suds used in dyeing operations and wool washing. In the indigo dyeing trade the spent vat liquors and wash waters after settlement gave a sludge containing so much indigo that it could be profitably re-used. In the manufacture of soap the spent lees were concentrated and distilled and the glycerine, which at one time was turned into the rivers, was now recovered. He considered that crude sewage should not be discharged into the open sea at low-water mark or into an estuary, more especially if the tidal currents were not sufficiently strong to remove or to dissipate the polluting matters without fear of their return. In the case of an estuary the sewage might be carried to sea very slowly and if discharged on the ebb tide might be carried only a short distance before it was driven back by the flood, and so oscillate backwards and forwards, causing a dangerous nuisance. Upon the vexed question of isolation hospital accommodation the President said that in his opinion a scarlet fever patient had a much better chance of recovery in an isolation hospital than in a cottage. He quite agreed that hospital isolation of scarlet fever patients had not quite answered the expectations that had been held out but he thought that no efficient sanitary authority could do without it. The non-removal policy had many attractions for parsimonious authorities, but he considered it wrong to endanger the health of neighbouring districts while engaged in the hopeless attempt to procure isolation in the ordinary dwellings of the working classes. In his remarks upon the administration of the Sale of Food and Drugs Acts he said that it was a grave reflection upon the Central Government that milk, the most important form of food so far as infants were concerned, should still continue to be subjected to frequent adulteration. The standard set up by the Board of Agriculture and Fisheries was, in his opinion, a good one, but its value was largely neutralised as it merely raised a presumption until the contrary was proved that the article was not genuine. He regretted that it was becoming increasingly difficult to obtain convictions in cases of alleged milk adulteration, and occasionally cases were dismissed by the magistrates even though no defence had been raised. In order to avoid such difficulties he considered that a fixed universal standard of genuineness should be adopted below which the sale of milk should be prohibited.

Æsculapian Society.—A meeting of this society was held on Nov. 20th, Dr. J. R. T. Conner, Vice-President, being in the chair.—Mr. Peter L. Daniel read a paper on the Treatment of Tuberculosis by Bier's Congestion and Hyperæmic Methods and by Injections of Iodoform Glycerine. He said that if they could mechanically obstruct the lymphatics and venules they were in possession of a valuable means of localising inflammatory processes and of thus protecting the whole body from invasion by bacteria and toxins, and "while limiting the process and protecting the body it permits nevertheless the whole body forces an opportunity to take part in the destruction of the germs." Iodoform glycerine acted in two ways: first, by mechanically obstructing the lymphatics; secondly, by inducing a hyperæmia—the reparative element of inflammation. By such obstruction to the lymph and venous flow a flooding of the diseased area with plasma took place, and however or wherever protective properties were manufactured in the living body they ultimately were conveyed by, and enabled to act through, the medium of the blood plasma; and as the arterial supply to the diseased area was quite unimpeded, this blood plasma charged with protective properties derived from the liver, spleen, marrow, and muscles permitted the whole body processes to be concentrated locally. By Bier's constricting bandage similar results were obtained in a more obvious manner, the essential point in this treatment being obstruction to the venous and lymphatic flow. Bier's methods consisted of (1) constriction by means of an elastic bandage; (2) suction by means of a suitable cupping glass; and (3) hot dry air. The constriction and suction produced lymphatic and venous congestion, but the hot air was said to induce an arterial hyperæmia. The constriction method, where it could be used, was the best method. The bandage used was made of elastic webbing, from 2 to 2½ inches wide; several turns of the bandage were made as far as convenient from the focus of disease until distinct fulness of the veins resulted. Such constriction must never be painful, or even uncomfortable; on the contrary, pain in the diseased area tended to be relieved and a sense of increased well-being resulted. Pallor and coldness beyond the bandage must never be produced, and if such result even after mild tension this should be evidence that the case was not suitable for constriction.—Dr. B. G. Morison showed a man with a Fracture of the Spine of the Scapula with two skiagrams.
